

UNSTABLE PATTERNS IN REACTION-DIFFUSION MODEL OF EARLY CARCINOGENESIS

ANNA MARCINIAK-CZUCHRA, GRZEGORZ KARCH, AND KANAKO SUZUKI

ABSTRACT. Motivated by numerical simulations showing the emergence of either periodic or irregular patterns, we explore a mechanism of pattern formation arising in the processes described by a system of a single reaction-diffusion equation coupled with ordinary differential equations. We focus on a basic model of early cancerogenesis proposed by Marciniak-Czochra and Kimmel [Comput. Math. Methods Med. **7** (2006), 189–213], [Math. Models Methods Appl. Sci. **17** (2007), suppl., 1693–1719], but the theory we develop applies to a wider class of pattern formation models with an autocatalytic non-diffusing component. The model exhibits diffusion-driven instability (Turing-type instability). However, we prove that all Turing-type patterns, *i.e.*, regular stationary solutions, are unstable in the Lyapunov sense. Furthermore, we show existence of discontinuous stationary solutions, which are also unstable.

1. INTRODUCTION

In this paper, we explore a mechanism of pattern formation arising in processes described by a system of a single reaction-diffusion equation coupled with ordinary differential equations. Such systems of equations arise from modeling of interactions between cellular processes and diffusing growth factors.

A rigorous derivation, using methods of asymptotic analysis (homogenization), of the macroscopic reaction-diffusion models describing the interplay between the nonhomogeneous cellular dynamics and the signaling molecules diffusing in the intercellular space has been recently published in [8]. It was shown that receptor-ligand binding processes can be modeled by reaction-diffusion equations coupled with ordinary differential equations in the case when all membrane processes are homogeneous within the membrane, which seems to be the case in most of processes. More precisely, such *receptor-based* models can be represented by the following initial-boundary value problem

$$\begin{aligned} u_t &= f(u, v), \\ v_t &= D\Delta v + g(u, v) && \text{in } \Omega, \\ \partial_n v &= 0 && \text{on } \partial\Omega, \\ u(x, 0) &= u_0(x), \\ v(x, 0) &= v_0(x), \end{aligned}$$

where u and v are vectors of variables, D is a diagonal matrix with positive coefficients on the diagonal, the symbol ∂_n denotes the normal derivative (no-flux condition), and Ω is a bounded region. It was shown that, if homogeneity of the processes on the membrane does not hold, equations with additional integral terms are obtained, see [8].

One of possible mechanisms of pattern formation in such models is *the diffusion-driven instability* (DDI), called also *the Turing-type instability*. Let us recall that the diffusion-driven instability arises in a reaction-diffusion system, when there exists a spatially homogeneous solution, which is asymptotically stable with respect to spatially homogeneous perturbations, but unstable to spatially inhomogeneous perturbation. Models with DDI describe the process of destabilization of a stationary spatially homogeneous state and evolution of spatially heterogeneous structures, which converge to a spatially heterogeneous steady state. The systems with DDI were prevalent in the modeling literature since the seminal paper of Turing [15] and have provided explanations of pattern formation in a variety of biological systems, see *e.g.* [10] and references therein.

The existing qualitative theory of such systems is mainly focused on stability conditions for homogeneous steady states. Moreover, the majority of theoretical studies focus on the analysis of the non-degenerated reaction-diffusion systems, *i.e.* with a strictly positive diffusion coefficient in each equation. However, in many biological applications, it is relevant to consider receptor-based systems involving ordinary differential equations. An interesting class of such systems consists of only a single reaction-diffusion equation coupled with a system of ordinary differential equations. The existence and stability of spatially heterogeneous patterns arising in models exhibiting diffusion-driven instability, but consisting of only one reaction-diffusion equation, is a mathematically interesting issue. Such models are very different from classical Turing-type models and the spatial structure of the pattern emerging from the destabilization of the spatially homogeneous steady state cannot be concluded based on linear stability analysis [10]. Asymptotic analysis of systems with such a dispersion relation seems to be an open problem.

In particular, such systems arise in the modeling of the growth of a spatially-distributed cell population, which proliferation is controlled by endogenous or exogenous growth factors diffusing in the extracellular medium and binding to cell surface as proposed by the first author and Kimmel in the series of recent papers [5, 6, 7]. The generic model has the following mathematical form of mixed reaction-diffusion and ordinary differential equations

$$(1.1) \quad u_t = (a_p(u, v) - d_c) u,$$

$$(1.2) \quad v_t = \alpha(u)w - dv - d_b v,$$

$$(1.3) \quad w_t = D\Delta w - d_g w - \alpha(u)w + dv + \kappa(u).$$

Here, unknown functions $u(x, t)$, $v(x, t)$, $w(x, t)$ describe the densities of cells, free and bound growth factor molecules, respectively, distributed over a certain bounded domain. In system (1.1)-(1.3), the proliferation rate $a_p(u, v)$, the growth factor binding rate $\alpha(u)$, and the production of the free growth factor by cells $\kappa(u)$ are given functions. We use the subscripts in the parameters d_c , d_b , d_g in order to emphasise that they denote the degradation factors of cells, bound molecules and growth molecules, respectively.

System (1.1)-(1.3) is usually supplemented with the homogeneous Neumann (zero flux) boundary conditions for the function $w = w(x, t)$ and with nonnegative initial conditions.

Based on preliminary mathematical analysis and using numerical simulations, the authors of [5, 6, 7] found conditions for the existence of a positive spatially homogeneous steady state exhibiting diffusion-driven instability. In numerical simulations instability of the constant steady state leads to the emergence of growth patterns concentrated around discrete points along the spatial coordinate, which take the mathematical form of spike-type spatially inhomogeneous solutions. This multifocality is as expected from the field

theory of carcinogenesis. Numerical simulations showed qualitatively new patterns of behavior of solutions, including, in some cases, a strong dependence of the emerging pattern on initial conditions and quasi-stability followed by rapid growth of solutions.

The main goal of this work is to develop mathematical theory that allows us to study properties of solutions to this kind of initial-boundary value problems. In this work, for simplicity of the exposition, we assume that cells occupy the interval $x \in [0, L]$ and we consider a particular form of functions a_p , α , κ , see the next section. Our results, however, hold true in a much more general case what we have systematically emphasized in our construction of patterns (see Section 5) and in the proof of their instability (Section 6).

The paper is organized as follows. In Section 2, main results of this paper are formulated. Section 3 is devoted to the existence of solutions. Section 4 provides preliminary results on the large time behavior of solutions and, in particular, a criterion on the pointwise extinction of solutions. In Section 5, nonhomogeneous stationary solutions are characterized and, in Section 6, instability of all stationary solutions is shown using linear stability analysis. The paper is supplemented by Appendix devoted to the analysis of the corresponding kinetics system (system of ordinary differential equations).

Notation. The usual norm of the Lebesgue space $L^p(0, 1)$ is denoted by $\|\cdot\|_p$ for any $p \in [1, \infty]$ and $W^{k,p}(0, 1)$ is the corresponding Sobolev space. The constants (always independent of x and t) will be denoted by the same letter C , even if they may vary from line to line. Sometimes, we write, *e.g.*, $C = C(p, q, r, \dots)$ when we want to emphasize the dependence of C on parameters $p, q, r, \dots$.

2. RESULTS AND COMENTS

2.1. Statement of the problem. In this work, we consider system (1.1)-(1.3) on the bounded interval $x \in [0, L]$. Moreover, in our mathematical analysis, we assume that the proliferation rate has the Hill function form

$$a_p(u, v) = a \frac{v/u}{1 + v/u} = \frac{av}{u + v}$$

with a given constant $a > 0$. We consider the quadratic growth factor binding rate $\alpha(u) = u^2$, which follows from conditions for the diffusion driven instability, see [5] and the next subsection for more details. Moreover, we assume that the production of the free growth factor is constant, $\kappa(u) \equiv \kappa_0 \geq 0$. This assumption is imposed for simplicity of the exposition; note that a more general case is also interesting from the modeling point of view, see [6]. Finally, we introduce the diffusion coefficient $1/\gamma$, which is a composite parameter including the diffusion constant $D > 0$ and the scaling parameter $L > 0$, namely, we set $\gamma = L^2/D$.

To summarize, we study the following system of three ordinary/partial differential equations

$$(2.1) \quad u_t = \left(\frac{av}{u + v} - d_c \right) u \quad \text{for } x \in [0, 1], \ t > 0,$$

$$(2.2) \quad v_t = -d_b v + u^2 w - dv \quad \text{for } x \in [0, 1], \ t > 0,$$

$$(2.3) \quad w_t = \frac{1}{\gamma} w_{xx} - d_g w - u^2 w + dv + \kappa_0 \quad \text{for } x \in (0, 1), \ t > 0$$

supplemented with the homogeneous Neumann (zero flux) boundary conditions for the function $w = w(x, t)$

$$(2.4) \quad w_x(0, t) = w_x(1, t) = 0 \quad \text{for all } t > 0$$

and with nonnegative initial conditions

$$(2.5) \quad u(x, 0) = u_0(x), \quad v(x, 0) = v_0(x), \quad w(x, 0) = w_0(x).$$

Here, the letters $a, d_c, d_b, d_g, d, \gamma, \kappa_0$ denote positive constants.

In Section 3, we show that the initial-boundary value problem (2.1)–(2.5) has a unique and global-in-time solution for a large class of nonnegative initial conditions. Such results on the global-in-time existence, the regularity of solutions, and their positivity for all $t > 0$ are rather standard for reaction-diffusion equations with non-zero diffusion in each equation, see *e.g.* [11] and the references therein. A more careful analysis is required in the case of the ODE-PDE system, hence, we state these results for the completeness of the exposition.

2.2. Diffusion-driven instability. We are interested in systems with the diffusion-driven instability. As it was stated in [7, Prop. 3.1], a generic system of two ordinary differential equations coupled with a reaction-diffusion equation, and such that $a_{ii} < 0$ for $i = 1, 2, 3$ and $a_{12}a_{21} > 0$, exhibits the diffusion-driven instability if there exists a positive, spatially constant steady state, for which the following conditions are satisfied

$$(2.6) \quad -\text{tr}(\mathcal{A}) > 0,$$

$$(2.7) \quad -\text{tr}(\mathcal{A}) \sum_{i < j} \det(\mathcal{A}_{ij}) + \det(\mathcal{A}) > 0,$$

$$(2.8) \quad -\det(\mathcal{A}) > 0,$$

$$(2.9) \quad -\det(\mathcal{A}_{12}) > 0,$$

where $\mathcal{A} = (a_{ij})_{i,j=1,2,3}$ is the Jacobian matrix of the system without diffusion linearized around this constant positive equilibrium and $\mathcal{A}_{ij}$ is a submatrix of $\mathcal{A}$ consisting of the i -th and j -th column and i -th and j -th row.

Conditions (2.6)–(2.8) are necessary for the stability of the steady state in the absence of diffusion. Inequality (2.9) is a sufficient and necessary condition for destabilization of this steady state in every system with all $a_{ii} < 0$ for $i = 1, 2, 3$ and $a_{12}a_{21} > 0$ (for the proof see [5]). These conditions guarantee that the model (1.1)–(1.3) exhibits diffusion-driven instability if the function $\alpha(u)$ evaluated at the steady state $\bar{u}$ satisfies $\alpha(\bar{u}) - \bar{u}\alpha'(\bar{u}) < 0$, what, in particular, always holds for $\alpha(u) = u^2$ in model (2.1)–(2.3).

In the particular case of system (2.1)–(2.3), conditions (2.6)–(2.9) hold true for the constant steady state $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$ defined in (2.12) (see the next subsection) and for the matrix $\mathcal{A}$ stated in (2.31) with $W = \bar{w}_-$. Note that condition (2.9) leads to 2 eigenvalues of the matrix $\mathcal{A}_{12}$ of an opposite sign. The positive eigenvalue of $\mathcal{A}_{12}$ plays the crucial role in the proof of instability of all steady states of system (2.1)–(2.3), see Subsection 2.5.

2.3. Preliminary properties of solutions. We begin our study of qualitative properties of solutions to problem (2.1)–(2.5) by considering x -independent solutions which satisfy the corresponding *kinetic system* of the three ordinary differential equations (see (A.1)–(A.3), below). Let us briefly summarize our results on the kinetic system that we prove in Appendix A.

- For every constant initial condition $\bar{u}(0) \geq 0$, $\bar{v}(0) \geq 0$, and $\bar{w}(0) \geq 0$, the problem (2.1)–(2.5) has a unique x -independent global-in-time solution $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$. This solution stays, for $t \geq 0$, in a bounded set, see Proposition A.1. Here, if $\bar{u}(t_0) = \bar{v}(t_0) = 0$ for certain $t_0 \geq 0$, the right-hand side of equation (2.1) is satisfied in the limit sense, namely, when $\bar{v} \searrow 0$ and $\bar{u} \searrow 0$.
- The constant vector

$$(2.10) \quad (\bar{u}_0, \bar{v}_0, \bar{w}_0) \equiv \left(0, 0, \frac{\kappa_0}{d_g}\right)$$

is a *trivial steady state* of system (2.1)–(2.3). This is an asymptotically stable solution not only of the kinetic system (A.1)–(A.3), but also of the reaction-diffusion equations (2.1)–(2.4), see Corollary 2.4 and Proposition 4.1. Moreover, in Theorems A.2–A.5 of Appendix, we describe convergence rates of solutions to the kinetic system towards the trivial steady states.

- Assume that $a > d_c$ and

$$(2.11) \quad \kappa_0^2 \geq \Theta, \quad \text{where} \quad \Theta = 4d_g d_b \frac{d_c^2(d_b + d)}{(a - d_c)^2}.$$

Then, system (2.1)–(2.3) has constant positive stationary solutions $(\bar{u}_\pm, \bar{v}_\pm, \bar{w}_\pm)$, where

$$(2.12) \quad \bar{w}_\pm = \frac{\kappa_0 \pm \sqrt{\kappa_0^2 - \Theta}}{2d_g}, \quad \bar{v}_\pm = \frac{d_c^2(d_b + d)}{(a - d_c)^2} \frac{1}{\bar{w}_\pm}, \quad \bar{u}_\pm = \frac{a - d_c}{d_c} \bar{v}_\pm.$$

- The stationary solution $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$ of the kinetic system (A.1)–(A.3) is asymptotically stable, namely, the linearization matrix of this system at the steady state $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$ has all eigenvalues with negative real parts. On the other hand, the steady state $(\bar{u}_+, \bar{v}_+, \bar{w}_+)$ is an unstable solution of (A.1)–(A.3), because its linearization matrix has one positive eigenvalue, see Theorem A.9 and Corollary A.10, for more details.

From now on, we consider solutions of problem (2.1)–(2.5) that are not necessarily space-inhomogeneous. Unlike in the case of the kinetic system (see Proposition A.1 in Appendix), in view of numerical simulations, we do not expect that such a solution stays in a certain invariant region as it is discussed in the monograph by Smoller [14, Ch. 14, §B]. However, in the following theorem, we prove that integrals of all nonnegative solutions of (2.1)–(2.5) enter, as $t \rightarrow \infty$, into a certain invariant set, which is independent of initial conditions. Notice that the mass of a solution is controlled for all $t > 0$ as in the survey article [11], where systems with non-zero diffusion in each equation were discussed.

Theorem 2.1. *Assume that (u, v, w) is a nonnegative global-in-time solution of problem (2.1)–(2.5) corresponding to a bounded initial condition $(u_0, v_0, w_0) \in L^1(0, 1) \times L^1(0, 1) \times L^\infty(0, 1)$. Denote $\mu = \min\{d_g, d_b\} > 0$. Then, the following estimates hold*

$$(2.13) \quad \limsup_{t \rightarrow \infty} \int_0^1 u(x, t) \, dx \leq \min \left\{ \frac{\kappa_0}{\mu}, \frac{a\kappa_0}{d_c\mu} \right\},$$

$$(2.14) \quad \limsup_{t \rightarrow \infty} \int_0^1 v(x, t) \, dx \leq \frac{\kappa_0}{\mu},$$

$$(2.15) \quad \limsup_{t \rightarrow \infty} \|w(t)\|_\infty \leq \kappa_0 \left(\frac{Cd}{\mu d_g^{1/2}} + \frac{1}{d_g} \right),$$

with a numeric constant $C > 0$ independent of problem (2.1)–(2.5).

This theorem is proved at the end of Section 3. Notice that it holds also true for $\kappa_0 = 0$, hence, in this particular case, each nonnegative solution of problem (2.1)-(2.5) satisfies $(\|u(t)\|_1, \|v(t)\|_1, \|w(t)\|_\infty) \rightarrow (0, 0, 0)$ as $t \rightarrow \infty$.

Next, we discuss the stability of the trivial steady state (2.10) as a solution of the reaction-diffusion equations (2.1)-(2.4). First of all, we have to emphasize that, under the assumption $a < d_c$, each nonnegative solution of problem (2.1)-(2.5) converges exponentially towards $(0, 0, \kappa_0/d_g)$, see Proposition 4.1 below. Hence, in this work, we have always to assume that $a \geq d_c$ to observe a nontrivial large time behavior of solutions.

It is clear from equation (2.1) that if $u_0(x) = 0$ for some $x \in [0, 1]$ then $u(x, t) = 0$ for all $t \geq 0$ and, by equation (2.2), we have $v(x, t) \rightarrow 0$ as $t \rightarrow \infty$. Furthermore, below in Proposition 4.2, we show that, for each $x \in [0, 1]$, the following two conditions

$$(2.16) \quad \lim_{t \rightarrow \infty} u(x, t) = 0 \quad \text{and} \quad \lim_{t \rightarrow \infty} v(x, t) = 0$$

are equivalent. The following result plays a fundamental role in understanding of the pattern formation described by problem (2.1)-(2.5) (see Remark 2.14, below) and says that relations (2.16) hold true if $u_0(x)$ and $v_0(x)$ are not too large.

Theorem 2.2. *Assume that $a > d_c$ and other coefficients in system (2.1)-(2.5) are positive and arbitrary. Fix $x \in [0, 1]$ and assume that there exist constants $K_w > 0$ and $M > 0$ satisfying*

$$(2.17) \quad MK_w \left(1 + \frac{d_c}{a}\right)^2 \leq (d_b + d) \left(\frac{d_c}{a}\right)^2.$$

and such that for all $t > 0$

$$(2.18) \quad 0 \leq w(x, t) \leq K_w \quad \text{and} \quad 0 \leq u_0(x) \leq M, \quad 0 \leq v_0(x) < \left(\frac{d_c}{a}\right)^2 M.$$

Then, $(u(x, t), v(x, t)) \rightarrow (0, 0)$ as $t \rightarrow \infty$. This is the uniform convergence for all $x \in [0, 1]$, for which inequalities (2.18) are satisfied.

Remark 2.3. It follows from Theorem 2.1 that $\|w(t)\|_\infty$ is a bounded function of $t > 0$, hence, one can always find a constant $K_w > 0$ with the property stated in Theorem 2.2. In fact, this constant can be chosen explicitly, see Remark 3.5 at the end of Section 3.

We conclude this subsection by a corollary of Theorem 2.2 on the asymptotic stability of the trivial steady state.

Corollary 2.4. *Let $a > d_c$ and other coefficients in system (2.1)-(2.5) be positive. Assume that there exist constants $K_w > 0$ and $M > 0$ satisfying (2.17) and (2.18) for all $x \in [0, 1]$. Then $(u(x, t), v(x, t), w(x, t)) \rightarrow (0, 0, \kappa_0/d_g)$ as $t \rightarrow \infty$ uniformly in x .*

Here, it has to be emphasized that system (2.1)-(2.5) cannot be linearized around the solution $(0, 0, \kappa_0/d_c)$, because of the singularity at $u = v = 0$ in equation (2.1). Hence, to prove the convergence of a solution towards the trivial steady state a direct method (based on the ordinary differential equations (2.1)-(2.2)) was invented, see the proof of Theorem 2.2 in Section 4.

2.4. Existence and nonexistence of patterns. Here, we describe stationary solutions of (2.1)-(2.4), namely, functions $(U(x), V(x), W(x))$ that satisfy the system

$$(2.19) \quad \left(\frac{aV}{U+V} - d_c \right) U = 0,$$

$$(2.20) \quad -d_b V + U^2 W - dV = 0,$$

$$(2.21) \quad \frac{1}{\gamma} W_{xx} - d_g W - U^2 W + dV + \kappa_0 = 0$$

and the boundary condition

$$(2.22) \quad W_x(0) = W_x(1) = 0.$$

Let us recall that, for every $\gamma > 0$, system (2.19)-(2.22) has the trivial solution $(\bar{u}_0, \bar{v}_0, \bar{w}_0) = (0, 0, \kappa_0/d_g)$. Moreover, if $\kappa_0^2 \geq \Theta$, see (2.11), we have two other constant stationary solutions $(\bar{u}_\pm, \bar{v}_\pm, \bar{w}_\pm)$ defined in (2.12).

In the nonhomogeneous case, first, we consider $U(x)$ and $V(x)$, which are positive for all $x \in [0, 1]$. Hence, under the assumption $a > d_c$, using equations (2.19)-(2.20) we obtain the following identities

$$(2.23) \quad U(x) = \frac{a - d_c}{d_c} V(x) \quad \text{and} \quad V(x) = \frac{d_c^2(d_b + d)}{(a - d_c)^2} \frac{1}{W(x)}.$$

Moreover, adding equations (2.20) and (2.21), and using relations (2.23) we obtain the following boundary-value problem for the function W :

$$(2.24) \quad \frac{1}{\gamma} W'' - d_g W - d_b \frac{d_c^2(d_b + d)}{(a - d_c)^2} \frac{1}{W} + \kappa_0 = 0,$$

$$(2.25) \quad W'(0) = W'(1) = 0.$$

Here, to simplify our notation, we introduce the function

$$(2.26) \quad h(w) = -d_g w - d_b \frac{d_c^2(d_b + d)}{(a - d_c)^2} \frac{1}{w} + \kappa_0$$

and we define number

$$(2.27) \quad \gamma_0 \equiv \frac{\pi^2}{h'(\bar{w}_-)} > 0,$$

where $\bar{w}_-$ is the constant from (2.12).

First, let us summarize our results (proved in Section 5) on the *nonexistence* of solutions either to system (2.19)-(2.22) or to boundary value problem (2.24)-(2.25).

- Under the assumption $a \leq d_c$, the trivial solution $(0, 0, \kappa_0/d_g)$ is the only nonnegative solution of problem (2.19)-(2.22), see Proposition 5.1.
- If $a > d_c$ and $\kappa_0^2 < \Theta$, then the boundary value problem (2.24)-(2.25) has no positive solutions, see Proposition 5.2.i. Hence again, the trivial solution is the only nonnegative solution of (2.19)-(2.22).
- If $a > d_c$ and $\kappa_0^2 = \Theta$, then the constant function $w \equiv \kappa_0/d_c$ is the only solution of (2.24)-(2.25), see Proposition 5.2.ii.
- Let $a > d_c$ and $\kappa_0^2 > \Theta$. The parameter γ_0 is the critical value of the diffusion coefficient in the sense that for $\gamma \leq \gamma_0$, the boundary value problem (2.24)-(2.25) has no non-constant solutions., see Theorem 5.6.

FIGURE 2.1. All positive solutions of problem (2.24)-(2.25) with $\gamma > 0$ satisfying $3^2\gamma_0 < \gamma < 4^2\gamma_0$.

Hence, continuous patterns, *i.e.*, *non-constant continuous positive solutions*, of system (2.19)-(2.22) can exist only if $a > d_c$, $\kappa_0^2 > \Theta$, and $\gamma > \gamma_0$. Here, we show that this is indeed the case.

Definition 2.5. Let $k \in \mathbb{N}$ and $k \geq 2$. We call a function $W \in C([0, 1])$ a *periodic function on $[0, 1]$ with k modes* if $W = W(x)$ is monotone on $[0, \frac{1}{k}]$ and if

$$(2.28) \quad W(x) = \begin{cases} W(x - \frac{2j}{k}) & \text{for } x \in [\frac{2j}{k}, \frac{2j+1}{k}] \\ W(\frac{2j+2}{k} - x) & \text{for } x \in [\frac{2j+1}{k}, \frac{2j+2}{k}] \end{cases}$$

for every $j \in \{0, 1, 2, 3, \dots\}$ such that $2j + 2 \leq k$.

We are now in a position to describe all possible nonnegative solution of the boundary value problem (2.24)-(2.25).

Theorem 2.6 (Existence of continuous patterns). Assume that $a > d_c$, $\kappa_0^2 > \Theta$, and $\gamma > \gamma_0$, where γ_0 is defined in (2.27). Consider the biggest $n \in \mathbb{N}$ such that $\gamma > n^2\gamma_0$. Then, the boundary value problem (2.24)-(2.25) has the following solutions:

- the constant steady states $\bar{w}_\pm$,
- a unique strictly increasing solution and a unique strictly decreasing solution,
- for each $k \in \{2, \dots, n\}$, a unique periodic solution W_k with k modes that is increasing on $[0, \frac{1}{k}]$ as well as its symmetric counterpart: $\widetilde{W}_k(x) \equiv W_k(1 - x)$.

There are no other positive solutions of the boundary value problem (2.24)-(2.25).

All positive solutions of problem (2.24)-(2.25) with γ satisfying assumptions of Theorem 2.6 for $n = 3$ are sketched in Fig. 2.1.

Remark 2.7. Using relations (2.23), we immediately obtain all solutions $(U(x), V(x), W(x))$ of system (2.19)-(2.22) such that $U(x) > 0$ and $V(x) > 0$ for all $x \in [0, 1]$.

Remark 2.8. It follows from the proof of Theorem 2.6 that non-constant solutions of problem (2.24)-(2.25) oscillate around the constant solution $\bar{w}_-$ and they are all below the constant $\bar{w}_+$.

In our construction of non-constant solutions of the boundary value problem (2.24)-(2.25), we use the well-known method from the classical mechanics that appears in the study of conservative systems with one degree of freedom (see *e.g.* the Arnold book [1]). In Section 5, we recall that approach for reader's convenience. Our main contribution to this theory consists in the fact that we have found the optimal value of the coefficient γ for which we have non-constant stationary solutions. Moreover, we prove that there is no other solutions, which is a consequence of the monotonicity of the function $T = T(E)$ defined in (5.8), below.

Our next goal is to discuss nonnegative solutions of (2.19)-(2.22) such that $U(x) = V(x) = 0$ on a certain set $\mathcal{I} \subset [0, 1]$ which we refer to as a *null set* of a solution (U, V, W) . Here, we do not expect W to be a C^2 -function and, in the following, we say that a vector $(U, V, W) \in L^\infty([0, 1]) \times L^\infty([0, 1]) \times C^1([0, 1])$ is a *weak solution* of system (2.19)-(2.22) if the algebraic equations (2.19)-(2.20) are satisfied for almost all $x \in [0, 1]$ and if

$$(2.29) \quad -\frac{1}{\gamma} \int_0^1 W'(x) \varphi'(x) dx + \int_0^1 (-d_g W(x) - U^2(x)W(x) + dV(x) + \kappa_0) \varphi(x) dx = 0$$

for all $\varphi \in C^1([0, 1])$.

Comparing to Theorem 2.6, the set of weak solutions is more complicated.

Theorem 2.9 (Existence of discontinuous patterns). *Assume that $a > d_c$ and $\kappa_0^2 > \Theta$. There exists a continuum of weak solutions of system (2.19)-(2.22) with some $\gamma > 0$. Each such a solution $(U, V, W) \in L^\infty(0, 1) \times L^\infty(0, 1) \times C^1([0, 1])$ has the following property: there exists a sequence $0 = x_0 < x_1 < x_2 < \dots < x_N = 1$ such that for each $k \in \{0, N-1\}$ either*

- *for all $x \in (x_k, x_{k+1})$, $U(x) = V(x) = 0$ and $W(x)$ satisfies $\frac{1}{\gamma}W'' - d_g W + \kappa_0 = 0$,*

or

- *for all $x \in (x_k, x_{k+1})$, $U(x) > 0$ and $V(x) > 0$ are given by relations (2.23), where the function W is a solution of equation (2.24).*

In Theorem 2.9, we do not attempt to classify all discontinuous stationary solutions (as it was done in the continuous case in Theorem 2.6), because they appear to be unstable solutions of the reaction diffusion equations (2.1)-(2.4), see the next subsection. Instead, in the proof of Theorem 2.9, we present a simple geometric argument which allows us to construct such discontinuous patterns. Analogous constructions, using either geometrical or analytical arguments can be found in [2, 9].

2.5. Instability of patterns. Finally, we discuss stability (in the sense of Lyapunov) of stationary solutions of system (2.1)-(2.4), which are constructed in Theorems 2.6 and 2.9, and surprisingly, we prove that they are all unstable. Let us be more precise.

First, we consider a stationary solution $(U(x), V(x), W(x))$ of (2.1)-(2.4) where $W(x)$ is one of the functions from Theorem 2.6 and $U(x) > 0$, $V(x) > 0$ are obtained from $W(x)$ via relations (2.23). As the usual practice, we linearize system (2.1)-(2.3) around the steady state $(U(x), V(x), W(x))$ to obtain a system with three linear evolution equations with the linear operator $\mathcal{L}$ defined formally by

$$(2.30) \quad \mathcal{L} \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \frac{1}{\gamma} \partial_x^2 \eta \end{pmatrix} + \mathcal{A} \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix},$$

where

$$(2.31) \quad \mathcal{A}(x) = (a_{ij}(x))_{i,j=1,2,3} \equiv \begin{pmatrix} d_c \left(\frac{d_c}{a} - 1 \right) & \frac{(a-d_c)^2}{a} & 0 \\ 2K & -d_b - d & \frac{K^2}{W^2(x)} \\ -2K & d & -d_g - \frac{K^2}{W^2(x)} \end{pmatrix},$$

with the constant $K \equiv U(x)W(x) = \frac{d_c(d_b+d)}{a-d_c}$, see the beginning of Section 6 for more details. We consider $\mathcal{L}$ as a linear operator in the Hilbert space $\mathcal{H} = L^2(0,1) \times L^2(0,1) \times L^2(0,1)$ with the domain $D(\mathcal{L}) = L^2(0,1) \times L^2(0,1) \times W^{2,2}(0,1)$.

It follows from direct calculations that the constant coefficient matrix

$$(2.32) \quad \mathcal{A}_{12} \equiv \begin{pmatrix} d_c \left(\frac{d_c}{a} - 1 \right) & \frac{(a-d_c)^2}{a} \\ 2K & -d_b - d \end{pmatrix}$$

obtained from $\mathcal{A}(x)$ after removing the last row and the last column, has two real eigenvalues of opposite sign. The positive eigenvalue λ_0 of $\mathcal{A}_{12}$ (given explicitly by formula (6.20)) plays the crucial role in the proof of instability of stationary solution to problem (2.1)-(2.4).

Theorem 2.10 (Instability of continuous patterns). *Consider the linear operator $\mathcal{L}$ defined in (2.30), where $W(x)$ be one of the functions from Theorem 2.6 and $U(x)$, $V(x)$ are obtained from $W(x)$ via relations (2.23), except the constant solution $(\bar{u}_+, \bar{v}_+, \bar{w}_+)$, see (2.12). Then, the positive eigenvalue λ_0 of the matrix $\mathcal{A}_{12}$ belongs to the continuous spectrum of the operator $\mathcal{L}$. Moreover, there exists a sequence $\{\lambda_n\}_{n \in \mathbb{N}}$ of positive eigenvalues of the operator $\mathcal{L}$ that satisfy $\lambda_n \rightarrow \lambda_0$ as $n \rightarrow \infty$.*

Remark 2.11. For simplicity of the exposition, the constant stationary solution $(\bar{u}_+, \bar{v}_+, \bar{w}_+)$ is excluded from Theorem 2.10, however, its instability is clear. Namely, it is an unstable solution of the kinetic system (A.1)–(A.3), see Corollary A.10.

Notice that, in order to present our idea in the simplest context, first, we prove Theorem 2.10 in the case of the constant stationary solution $(U(x), V(x), W(x)) = (\bar{u}_-, \bar{v}_-, \bar{w}_-)$, see Theorem 6.4, below.

Corollary 2.12. *Every continuous stationary solution (U, V, W) considered in Theorem 2.10 is an unstable solution of the nonlinear system (2.1)-(2.4).*

This corollary results immediately from the classical theory. Indeed, by Theorem 2.10, every continuous stationary solution of system (2.1)-(2.4) is linearly unstable because the corresponding operator $\mathcal{L}$ has infinitely many positive eigenvalues. Now, it suffices to note that $-\mathcal{L}$ is a sectorial operator, see the monograph by Henry [3], hence, applying the general result from [3, Thm. 5.1.3] we show that (U, V, W) is an unstable solution of (2.1)-(2.4).

Next, we show the instability of discontinuous stationary solutions from Theorem 2.9. First, we have to emphasize that a direct linearization of system (2.1)-(2.4) is not possible at a weak stationary solution satisfying $U(x) = V(x) = 0$ at some $x \in [0, 1]$. This is a consequence of the fact that the gradient of the nonlinear term in equation (2.1) is not well-defined when $u = v = 0$, see the Jacobian matrix (6.2), below. Hence, we modify our proof of instability in the following way.

Let $(U_{\mathcal{I}}(x), V_{\mathcal{I}}(x), W_{\mathcal{I}}(x))$ be weak solution of (2.19)-(2.22) with a null set $\mathcal{I} \subset [0, 1]$, namely, we assume that

$$U_{\mathcal{I}}(x) = V_{\mathcal{I}}(x) = 0 \quad \text{for } x \in \mathcal{I} \quad \text{and} \quad U_{\mathcal{I}}(x) > 0, V_{\mathcal{I}}(x) > 0 \quad \text{for } x \in [0, 1] \setminus \mathcal{I}.$$

Let us exclude the case $\mathcal{I} = [0, 1]$, where the constant vector $(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}}) = (0, 0, \kappa_0/d_g)$ is asymptotically stable solution of (2.1)-(2.4) by Corollary 2.4. For a null set $\mathcal{I}$, we define the associate L^2 -space

$$L_{\mathcal{I}}^2(0, 1) = \{v \in L^2(0, 1) : v(x) = 0 \text{ for } x \in \mathcal{I}\},$$

supplemented with the usual L^2 -scalar product, which is a Hilbert space as the closed subspace of $L^2(0, 1)$. Obviously, when the measure of $\mathcal{I}$ equals zero, we have $L_{\mathcal{I}}^2(0, 1) = L^2(0, 1)$, thus, we assume in the following that $\mathcal{I}$ has a positive Lebesgue measure and is different from the whole interval.

Now, observe that if $u_0(x) = v_0(x) = 0$ for some $x \in [0, 1]$ then by equations (2.1)-(2.2), we have $u(x, t) = v(x, t) = 0$ for all $t \geq 0$. Hence, in view of Theorem 3.1, the space

$$(2.33) \quad \mathcal{H}_{\mathcal{I}} = L_{\mathcal{I}}^2(0, 1) \times L_{\mathcal{I}}^2(0, 1) \times L^2(0, 1)$$

is invariant for the flow generated by system (2.1)-(2.4) (notice that there is no “ $\mathcal{I}$ ” in the last coordinate of $\mathcal{H}_{\mathcal{I}}$). The crucial part of our analysis is based on the fact that, as long as we work in the space $\mathcal{H}_{\mathcal{I}}$, we can linearize system (2.1)-(2.4) at a discontinuous steady state $(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}})$. Moreover, for each $x \in [0, 1] \setminus \mathcal{I}$, the corresponding linearized operator agrees with $\mathcal{L}$ defined in (2.30) with the matrix $\mathcal{A}(x)$ from (2.31). Hence, the analysis from the proof of Theorem 2.10 can be directly adapted to discontinuous steady states and we obtain the following counterpart of Corollary 2.12.

Corollary 2.13. *Every discontinuous weak stationary solution $(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}})$ of problem (2.19)-(2.22) with a null set $\mathcal{I} \subset [0, 1]$, which was constructed in Theorem 2.9, is an unstable solution of the nonlinear system (2.1)-(2.4), considered in the Hilbert space $\mathcal{H}_{\mathcal{I}}$.*

Remark 2.14. In other words, the instability described by Corollary 2.13 appears when we perturb a stationary solution $(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}})$ on the set $[0, 1] \setminus \mathcal{I}$, namely, in those points where $U_{\mathcal{I}}$ and $V_{\mathcal{I}}$ are nonzero. On the other hand, by Theorem 2.2, small perturbations of this steady state on the null set $\mathcal{I}$, leads to a solution satisfying $u(x, t) \rightarrow 0$ and $v(x, t) \rightarrow 0$ as $t \rightarrow \infty$, for each $x \in \mathcal{I}$.

The proofs of Theorem 2.10 and Corollary 2.13 are given in Section 6.

2.6. Pattern formation. A natural question arises if our model exhibits a formation of any pattern, which persist for long times. Numerical simulations indicating the growth of such, computationally stable, spatially heterogeneous solutions were performed in [5, 6, 7]. The observed patterns take form of either periodic or irregular spikes and, now, it is clear that they cannot be described by stationary solutions, neither by smooth one from Theorem 2.6 nor discontinuous one provided by Theorem 2.9. Our present research is focused on understating these phenomena and answering questions on pattern formation in these kind of models.

3. EXISTENCE OF SOLUTIONS

We begin our study of properties of solutions to the initial value problem (2.1)-(2.5) by showing that it has a unique and global-in-time solution for all bounded and nonnegative initial conditions.

Theorem 3.1. *Assume that initial conditions $u_0, v_0 \in L^\infty(0, 1)$ and $w_0 \in W^{1,2}(0, 1)$ are nonnegative. Then, for every $T > 0$, the initial value problem (2.1)-(2.5) has a unique, global-in-time, nonnegative solution $u \in C([0, T], L^\infty(0, 1))$, $v \in C([0, T], L^\infty(0, 1))$ and $w \in C([0, T], W^{1,2}(0, 1))$ such that $u(x, \cdot), v(x, \cdot) \in C^1([0, T])$ for every $x \in [0, 1]$ and $w \in C^1([0, T]; W^{1,2}(0, 1)) \cap C((0, T]; W^{2,2}(0, 1))$.*

Remark 3.2. We can improve regularity of solutions using results from [13, p. 112] in the following way. Assume that there exists $\alpha \in (0, 1)$ such that $u_0, v_0 \in C^\alpha(0, 1)$ for some $\alpha \in (0, 1)$ and if $w_0 \in C^{2+\alpha}(0, 1)$ satisfies $(w_0)_x(0) = (w_0)_x(1) = 0$. Suppose, moreover, that $u_0(x) > 0$, $v_0(x) > 0$, and $w_0(x) \geq 0$ for all $x \in [0, 1]$. Then, the initial value problem (2.1)-(2.5) has a unique, global-in-time, and nonnegative solution $u, v \in C^{\alpha, 1+\alpha/2}([0, 1] \times [0, T])$ and $w \in C^{2+\alpha, 1+\alpha/2}([0, 1] \times [0, T])$ for every $T > 0$.

The proof of Theorem 3.1 is more-or-less standard and we recall it for the completeness of the exposition. Below, we have only sketched the reasoning and we refer the reader to [13, pp. 108-123] for other details.

First, we state a result on the local-in-time existence of solutions to the following initial-boundary value problem

$$(3.1) \quad u_t = f_1(u, v) \equiv \left(\frac{av}{|u| + |v|} - d_c \right) u,$$

$$(3.2) \quad v_t = f_2(u, v, w) \equiv -d_b v + u^2 w - dv,$$

$$(3.3) \quad w_t = \frac{1}{\gamma} w_{xx} - d_g w + f_3(u, v, w) \equiv \frac{1}{\gamma} w_{xx} - d_g w - u^2 w + dv + \kappa_0,$$

supplemented with the homogeneous Neumann boundary conditions

$$(3.4) \quad w_x(0, t) = w_x(1, t) = 0 \quad \text{for all } t > 0$$

and with initial conditions

$$(3.5) \quad u(x, 0) = u_0(x), \quad v(x, 0) = v_0(x), \quad w(x, 0) = w_0(x).$$

Lemma 3.3. *Let $u_0, v_0 \in L^\infty(0, 1)$ and $w_0 \in W^{1,2}(0, 1)$. There exists $T_0 > 0$ such that the initial value problem (3.1)-(3.5) has a unique local-in-time solution*

$$u \in C([0, T], L^\infty(0, 1)), \quad v \in C([0, T], L^\infty(0, 1)) \quad \text{and} \quad w \in C([0, T], W^{1,2}(0, 1)).$$

Proof. Here, it suffices to apply the abstract results by Rothe [13, Thm. 1, p. 111]. We recall that a *mild* solution (u, v, w) of problem (3.1)-(3.5), on a time interval $[0, T]$ and with initial data $u_0, v_0, w_0 \in L^\infty(0, 1)$, are measurable functions $u, v, w : (0, 1) \times (0, T) \rightarrow \mathbb{R}$ satisfying the following system of integral equations

$$(3.6) \quad u(x, t) = u_0(x) + \int_0^t f_1(u(x, s), v(x, s)) ds,$$

$$(3.7) \quad v(x, t) = v_0(x) + \int_0^t f_2(u(x, s), v(x, s), w(x, s)) ds,$$

$$(3.8) \quad w(x, t) = S(t)w_0(x) + \int_0^t S(t-s)(f_3(u, v, w))(x, s) ds,$$

where $S(t)$ is a semigroup of linear operators associated with the equation $Z_t = \gamma^{-1} Z_{xx} - d_g Z$ on the interval $(0, 1)$, with the Neumann boundary conditions. Observe that the function $f_1 = f_1(u, v)$ in equation (3.1) is Lipschitz continuous if we put $f_1(0, 0) = 0$. Hence, to construct local-in-time solutions of system (3.6)-(3.8), it suffices to apply the contraction mapping principle based on the Picard iterations. Details of such reasoning can be found in [13, Thm. 1, p. 111]. $\square$

Next, we show that the solutions are nonnegative.

Lemma 3.4. *Let the assumptions of Lemma 3.3 hold true. Assume that (u, v, w) is a solution of problem (3.1)–(3.5) on a certain interval $[0, T]$. If u_0, v_0 and w_0 are nonnegative, then $u(x, t), v(x, t)$ and $w(x, t)$ are nonnegative for all $x \in [0, 1]$ and $t \in [0, T]$.*

Proof. Step 1. First, notice that the inequality $w(x, t) \geq 0$ for all $x \in [0, 1]$ and $t \in [0, T]$ implies $v(x, t) \geq 0$ for all $x \in [0, 1]$ and $t \in [0, T]$. Indeed, using equation (3.2) with nonnegative w we obtain the inequality $v_t(x, t) \geq -(d_b + d)v(x, t)$, which implies $v(x, t) \geq e^{-(d_b + d)T}v_0(x)$ for all $x \in [0, 1]$ and $t \in [0, T]$.

Step 2. Without loss of generality, we can assume that $w_0(x) > 0$. Indeed, it suffices to replace w_0 by $w_0 + \varepsilon$ with $\varepsilon > 0$ and to use the continuous dependence of solutions of problem (3.1)–(3.5) on initial conditions.

For $w_0(x) > 0$, by the continuity of w (see Lemma 3.3), we obtain $w(x, t) > 0$ for all $x \in [0, 1]$ and for sufficiently small $t > 0$. Suppose there are $x_0 \in [0, 1]$ and $t_0 > 0$ such that $w(x, t) > 0$ for $x \in [0, 1]$ and $t \in [0, t_0)$ and such that $w(x_0, t_0) = 0$. Note that $\sup_{0 \leq t \leq t_0} \|u(t)\|_\infty \leq M$ for some constant $M > 0$ by Lemma 3.3 and $v(x, t) \geq 0$ for all $x \in [0, 1]$ and $t \in [0, t_0]$ by Step 1. Hence, using equation (3.3) we obtain

$$w_t \geq \frac{1}{\gamma} w_{xx} - d_g w - M^2 w + \kappa_0.$$

In this inequality, all derivatives make sense, because, by a standard regularity theory for parabolic equation, we obtain

$$w \in C^1([0, t_0], W^{1,2}(0, 1)) \cap C((0, t_0], W^{2,2}(0, 1)).$$

Since $\kappa_0 > 0$, by a comparison principle, we obtain $w(x, t) > 0$ for all $x \in [0, 1]$ and $t \in [0, t_0]$, which contradicts our hypothesis $w(x_0, t_0) = 0$.

Step 3. Let us finally find the lower bound for u . As long as $v = v(x, t)$ is nonnegative, it follows from equation (3.1) that $u_t(x, t) \geq -d_c u(x, t)$. Integrating this differential inequality we arrive at the estimate $u(x, t) \geq e^{-d_c t} u_0(x)$ for all $x \in [0, 1]$ and $t \in [0, t_1]$. $\square$

Proof of Theorem 3.1. Obviously, as long as a solution (u, v, w) of (3.1)–(3.5) is nonnegative, it is also a solution of our original problem (2.1)–(2.5).

As the usual practice, to prove that local-in-time solutions from Lemma 3.3 exists for all $t > 0$, it suffices to show that for every $T > 0$

$$\sup_{t \in [0, T)} (\|u(t)\|_\infty + \|v(t)\|_\infty + \|w(t)\|_\infty) < \infty,$$

see *eg.* [13, Thm. 1.iii, p. 111] for more details.

For positive u and v , we have $v/(u + v) \leq 1$, hence, it follows from equation (2.1) that $u_t(x, t) \leq (a - d_c)u(x, t)$ for all $x \in [0, 1]$ and $t \in [0, T)$. Integrating this differential inequality we obtain

$$(3.9) \quad \sup_{t \in [0, T)} \|u(t)\|_\infty \leq e^{(a - d_c)T} \|u_0\|_\infty \quad \text{for every } T > 0.$$

Next, we use the integral equation (3.7) for v . Computing the L^∞ -norm and using (3.9) we obtain

$$(3.10) \quad \|v(t)\|_\infty \leq \|v_0\|_\infty + \int_0^t ((d_b + d)\|v(s)\|_\infty + C(T)\|w(s)\|_\infty) ds,$$

where, following (3.9), we denote $C(T) = e^{2(a - d_c)T} \|u_0\|_\infty^2$.

In a similar way, computing the L^∞ -norm of the integral equation (3.8) and using the well-known properties of the semigroup $S(t)$ we obtain

$$(3.11) \quad \|w(t)\|_\infty \leq \|w_0\|_\infty + \kappa_0 + \int_0^t (d\|v(s)\|_\infty + C(T)\|w(s)\|_\infty) ds.$$

Finally, adding inequalities (3.10) and (3.11) and using the Gronwall lemma, we complete the proof that $\sup_{t \in [0, T]} (\|v(t)\|_\infty + \|w(t)\|_\infty) < \infty$ for every $T > 0$. $\square$

Proof of Theorem 2.1. Integrating both sides of equations (2.2) and (2.3) with respect to $x \in [0, 1]$, adding the resulting formulas, and putting $\mu = \min\{d_g, d_b\}$, we obtain the differential inequality

$$\frac{d}{dt} \int_0^1 (v(x, t) + w(x, t)) dx \leq -\mu \int_0^1 (v(x, t) + w(x, t)) dx + \kappa_0.$$

Therefore,

$$(3.12) \quad \int_0^1 (v(x, t) + w(x, t)) dx \leq \left(\int_0^1 (v_0(x) + w_0(x)) dx \right) e^{-\mu t} + \frac{\kappa_0}{\mu} (1 - e^{-\mu t}),$$

which implies (2.14) and the bound by κ_0/μ in (2.13), because v, w are nonnegative.

To show the second bound in (2.13), notice that, for nonnegative u, v , we have $u/(u + v) \leq 1$, hence, it follows from equation (2.1) that $u_t \leq -d_c u + av$. Integrating this differential inequality, we obtain that the functions $\mathcal{U}(t) \equiv \int_0^1 u(x, t) dx$ and $\mathcal{V}(t) \equiv \int_0^1 v(x, t) dx$ satisfy

$$(3.13) \quad \mathcal{U}(t) \leq e^{-d_c t} \mathcal{U}(0) + a \int_0^t e^{-d_c(t-s)} \mathcal{V}(s) ds.$$

Since $\mathcal{V}$ is a bounded function and $d_c > 0$, we immediately obtain

$$\int_0^{t/2} e^{-d_c(t-s)} \mathcal{V}(s) ds \leq e^{-d_c t/2} \int_0^{t/2} \mathcal{V}(s) ds \rightarrow 0 \quad \text{as } t \rightarrow \infty.$$

On the other hand, we have

$$\int_{t/2}^t e^{-d_c(t-s)} \mathcal{V}(s) ds \leq \left(\sup_{s \in [t/2, t]} \mathcal{V}(s) \right) \frac{1}{d_c} (1 - e^{-d_c t/2}),$$

where $\lim_{t \rightarrow \infty} \sup_{s \in [t/2, t]} \mathcal{V}(s) \leq \kappa_0/\mu$ by (2.14). Hence, computing the limit superior as $t \rightarrow \infty$ of both sides of inequality (3.13), we complete the proof of (2.13).

Next, let $B(x, y, t)$ be the fundamental solution of the equation $Z_t = \gamma^{-1} Z_{xx} - d_g Z$ for $x \in (0, 1)$ and $t > 0$, supplemented with the Neumann boundary condition. It is well known (see *e.g.* [13, pp. 19 & 25]) that $B(x, y, t)$ is nonnegative,

$$(3.14) \quad \int_0^1 B(x, y, t) dy \leq e^{-d_g t} \quad \text{for all } x \in [0, 1], t > 0,$$

and there exists a constant $C > 0$ such that

$$(3.15) \quad \int_0^1 B(x, y, t) v(y) dy \leq C t^{-1/2} e^{-d_g t} \|v\|_1$$

for each $v \in L^1(0, 1)$, all $x \in [0, 1]$, and $t > 0$. Hence, equation (2.3) can be written as the following integral equation

$$(3.16) \quad w(x, t) = \int_0^1 B(x, y, t) w_0(y) dy + \int_0^t \int_0^1 B(x, y, t-s) (-u^2(y, s) w(y, s) + d v(y, s) + \kappa_0) dy ds$$

which, in view of the positivity of B , w , v , via inequalities (3.14), implies

$$(3.17) \quad \|w(t)\|_\infty \leq \|w_0\|_\infty e^{-d_g t} + d \int_0^t \int_0^1 B(x, y, t-s) v(y, s) dy ds + \frac{\kappa_0}{d_g} (1 - e^{-d_g t}).$$

Moreover, it follows from (3.12) and (3.15) that the second term on the right-hand side of (3.17) can be estimated as

$$(3.18) \quad \begin{aligned} d \int_0^t \int_0^1 B(x, y, t-s) v(y, s) dy ds &\leq dC \int_0^t (t-s)^{-1/2} e^{-d_g(t-s)} \|v(s)\|_1 ds \\ &\leq dC (\|v_0\|_1 + \|w_0\|_1) \int_0^t (t-s)^{-1/2} e^{-d_g(t-s)} e^{-\mu s} ds \\ &\quad + dC \frac{\kappa_0}{\mu} \int_0^t (t-s)^{-1/2} e^{-d_g(t-s)} (1 - e^{-\mu s}) ds. \end{aligned}$$

It is easy to prove that $\lim_{t \rightarrow \infty} \int_0^t (t-s)^{-1/2} e^{-d_g(t-s)} e^{-\mu s} ds = 0$ and

$$\limsup_{t \rightarrow \infty} \int_0^t (t-s)^{-1/2} e^{-d_g(t-s)} (1 - e^{-\mu s}) ds = d_g^{-1/2} \int_0^\infty s^{-1/2} e^{-s} ds.$$

Hence, the limit relation in (2.15) is immediately obtained from (3.17) and (3.18). $\square$

Remark 3.5. By an inspection of the proof of Theorem 2.1, we obtain the following global-in-time estimate of $w = w(x, t)$:

$$(3.19) \quad \|w(t)\|_\infty \leq \|w_0\|_\infty + Cd \left(2 + \frac{1}{d_g} \right) \left(\|v_0\|_1 + \|w_0\|_1 + \frac{\kappa_0}{\mu} \right),$$

where C and μ are the constants from (3.18).

4. LARGE TIME BEHAVIOR OF SOLUTIONS

In this section, we prove preliminary results on the large time behavior of solutions of problem (2.1)-(2.5). Let us first prove that, under the assumption $a < d_c$, each positive solution of system (2.1)-(2.3) converges exponentially towards the trivial steady state $(0, 0, \kappa_0/d_g)$.

Proposition 4.1. *Let $a < d_c$. Assume that (u, v, w) is a nonnegative global-in-time solution of problem (2.1)-(2.5) corresponding to a bounded initial condition. Then, there exist positive constants $C_1, C_2, \sigma_1, \sigma_2$ dependent on the parameters in system (2.1)-(2.5)*

and C_2 dependent also on $\|u_0\|_\infty$ and $\|v_0\|_\infty$, such that

$$(4.1) \quad 0 \leq u(x, t) \leq u_0(x) e^{-(d_c - a)t},$$

$$(4.2) \quad 0 \leq v(x, t) \leq v_0(x) e^{-(d_b + d)t} + C_1 u_0^2(x) t e^{-\sigma_1 t},$$

$$(4.3) \quad \left\| w(\cdot, t) - \frac{\kappa_0}{d_g} \right\|_{L^\infty} \leq C_2 e^{-\sigma_2 t},$$

for all $x \in [0, 1]$ and $t \geq 0$.

Proof. Since u and v are nonnegative, we have $v/(u + v) \leq 1$. Hence, we easily deduce from equation (2.1) the following inequality $u_t(x, t) \leq -(d_c - a)u(x, t)$, which implies estimate (4.1).

Since Theorem 2.1 yields $K_w \equiv \sup_{t \geq 0} \|w(t)\|_\infty < \infty$, then using equation (2.2) and estimate (4.1), we obtain the differential inequality

$$(4.4) \quad v_t(x, t) \leq -(d_b + d)v(x, t) + K_w u_0^2(x) e^{-2(d_c - a)t},$$

which implies (4.2).

To show the exponential convergence of $w = w(x, t)$ towards κ_0/d_g stated in (4.3), it suffices to use the integral representation (3.16) of w , inequalities (4.1) and (4.2), and to follow estimates from the proof of Corollary 2.4, below. $\square$

Proposition 4.2. *Assume that $(u(x, t), v(x, t), w(x, t))$ is a nonnegative solution of problem (2.1)-(2.5). Fix $x \in [0, 1]$. The following two conditions are equivalent*

$$(i) \quad u(x, t) \rightarrow 0 \quad \text{as} \quad t \rightarrow \infty \quad \text{and} \quad (ii) \quad v(x, t) \rightarrow 0 \quad \text{as} \quad t \rightarrow \infty.$$

Proof. We rewrite equation (2.2) in the following integral form

$$v(x, t) = e^{-(d_b + d)t} v_0(x) + \int_0^t e^{-(d_b + d)(t-s)} u^2(x, s) w(x, s) ds.$$

By Theorem 2.1, the function $w(x, t)$ is bounded for $x \in [0, 1]$ and $t \geq 0$, hence, combining condition (i) with the Lebesgue dominated convergence theorem in this integral equation, we can prove (ii).

Recall that for nonnegative u and v we have $u/(u + v) \leq 1$. Hence, it follows from equation (2.1) that $u_t(x, t) \leq -d_c u(x, t) + a v(x, t)$. Integrating this differential inequality and following the previous argument we prove directly that (ii) implies (i). $\square$

Before proving Theorem 2.2, in the following lemma, we show a kind of pointwise stability of the trivial steady state.

Lemma 4.3. *Let $x \in [0, 1]$. Under the assumptions of Theorem 2.2, it holds*

$$(4.5) \quad 0 \leq u(x, t) < M \left(1 + \frac{d_c}{a} \right) \quad \text{and} \quad 0 \leq v(x, t) < \left(\frac{d_c}{a} \right)^2 M$$

for all $t > 0$.

Proof. Recall that the nonnegativity of u and v has been shown already in Lemma 3.4.

Step 1. First, we suppose that there is $T > 0$ such that $u(x, t) \leq M(1 + d_c/a)$ for all $t \in [0, T]$. Remember that $0 \leq w(x, t) \leq K_w$ for all $x \in [0, 1]$ and $t \geq 0$. Hence, it follows

from equation (2.2) satisfied by v that

$$\begin{aligned}
 \frac{\partial}{\partial t} \left(v(x, t) - \left(\frac{d_c}{a} \right)^2 M \right) &= - (d_b + d) \left(v(x, t) - \left(\frac{d_c}{a} \right)^2 M \right) + u^2 w \\
 &\quad - (d_b + d) \left(\frac{d_c}{a} \right)^2 M \\
 (4.6) \qquad &\leq - (d_b + d) \left(v(x, t) - \left(\frac{d_c}{a} \right)^2 M \right) \\
 &\quad + \left[M^2 \left(1 + \frac{d_c}{a} \right)^2 K_w - (d_b + d) \left(\frac{d_c}{a} \right)^2 M \right].
 \end{aligned}$$

The term in the brackets on the right hand side of (4.6) is non-positive, because of assumption (2.17), hence, we skip it. Integrating the resulting differential inequality, we obtain

$$(4.7) \qquad v(x, t) - \left(\frac{d_c}{a} \right)^2 M \leq e^{-(d_b+d)t} \left(v_0(x) - \left(\frac{d_c}{a} \right)^2 M \right)$$

for all $t \in [0, T]$. Using the assumption of $v_0(x)$ stated in (2.18), we see that the right-hand side of (4.7) is negative, hence, we obtain

$$v(x, t) < \left(\frac{d_c}{a} \right)^2 M \quad \text{for all } t \in [0, T].$$

Step 2. Now, suppose that there is $T > 0$ such that $v(x, t) \leq (d_c/a)^2 M$ for all $t \in [0, T]$. Applying the inequality $u/(u+v) \leq 1$ in equation (2.1) yields

$$u_t(x, t) \leq av(x, t) - d_c u(x, t) \leq a \left(\frac{d_c}{a} \right)^2 M - d_c u(x, t).$$

Integrating this differential inequality and using the assumption on $u_0(x)$ from (2.18), we obtain

$$(4.8) \qquad u(x, t) \leq e^{-d_c t} u_0(x) + \frac{a}{d_c} \left(\frac{d_c}{a} \right)^2 M (1 - e^{-d_c t}) < M \left(1 + \frac{d_c}{a} \right)$$

for all $t \in [0, T]$.

Conclusion. By Theorem 3.1, for each $x \in [0, 1]$, the functions $u(x, t)$ and $v(x, t)$ are continuous with respect to t . Suppose that inequalities (4.5) hold true for all $t \in [0, T]$ with some $T > 0$ and at least one of them becomes an equality for $t = T$. Such a hypothesis, however, contradicts either the implication from Step 1 or from Step 2. This completes the proof of Lemma 4.3. $\square$

Proof of Theorem 2.2. We are going to construct a sequence $\{T_{2n}\}_{n \geq 1}$, independent of $x \in [0, 1]$, satisfying $T_{2n} < T_{2(n+1)}$ and $\lim_{n \rightarrow \infty} T_{2n} = +\infty$, such that $u(x, t)$ and $v(x, t)$ fulfill for each $n \in \mathbb{N}$ the following inequalities

$$(4.9) \quad u(x, t) \leq \theta^{n-1} \frac{d_c}{a} \left(1 + \frac{d_c}{a} \right) M \quad \text{and} \quad v(x, t) \leq \theta^n \left(\frac{d_c}{a} \right)^2 M \quad \text{for all } t \geq T_{2n}.$$

Here $\theta \equiv [1 + (d_c/a)^2]/2 < 1$, because of the assumption $d_c < a$. Since u and v are nonnegative, inequalities (4.9) imply $\lim_{t \rightarrow \infty} u(x, t) = \lim_{t \rightarrow \infty} v(x, t) = 0$.

We proceed by induction with respect to n .

Step 1. By Lemma 4.3, we have $v(x, t) < (d_c/a)^2 M$ for all $t > 0$. The first inequality in (4.8) and the assumption on $u_0(x)$ lead to the estimates

$$(4.10) \quad u(x, t) \leq e^{-d_c t} u_0(x) + \frac{a}{d_c} \left(\frac{d_c}{a} \right)^2 M (1 - e^{-d_c t}) \leq e^{-d_c t} M + \frac{d_c}{a} M (1 - e^{-d_c t}).$$

Hence, choosing $T_1 > 0$ such that $e^{-d_c t} M \leq \left(\frac{d_c}{a} \right)^2 M$ for all $t \geq T_1$ we obtain

$$(4.11) \quad u(x, t) \leq \frac{d_c}{a} M \left(1 + \frac{d_c}{a} \right) \quad \text{for all } t \geq T_1.$$

Consequently, it follows from the differential equation (2.2) and from the assumption on $w(x, t)$ that

$$(4.12) \quad v_t(x, t) \leq -(d_b + d)v + \left[\frac{d_c}{a} M \left(1 + \frac{d_c}{a} \right) \right]^2 K_w \quad \text{for all } t \geq T_1.$$

Integrating this differential inequality for $t \geq T_1$, we obtain

$$(4.13) \quad v(x, t) \leq e^{-(d_b+d)(t-T_1)} v(x, T_1) + \frac{\left(\frac{d_c}{a} \right)^2 M^2 \left(1 + \frac{d_c}{a} \right)^2 K_w}{d_b + d} (1 - e^{-(d_b+d)(t-T_1)}).$$

Using the assumption (2.17), written in the form

$$\frac{\left(\frac{d_c}{a} \right)^2 M^2 \left(1 + \frac{d_c}{a} \right)^2 K_w}{d_b + d} \leq \left(\frac{d_c}{a} \right)^4 M,$$

and the inequality $v(x, T_1) \leq (d_c/a)^2 M$ from Lemma 4.3, we obtain from (4.13) that

$$(4.14) \quad v(x, t) \leq e^{-(d_b+d)(t-T_1)} \left(\frac{d_c}{a} \right)^2 M + \left(\frac{d_c}{a} \right)^4 M \quad \text{for all } t \geq T_1.$$

Now, we choose $T_2 > T_1$ such that

$$e^{-(d_b+d)(t-T_1)} \left(\frac{d_c}{a} \right)^2 M \leq \frac{1}{2} \left(\left(\frac{d_c}{a} \right)^2 M - \left(\frac{d_c}{a} \right)^4 M \right) \quad \text{for all } t \geq T_2.$$

Therefore, the right-hand side of (4.14) is estimated as

$$v(x, t) \leq \frac{1}{2} \left(1 - \left(\frac{d_c}{a} \right)^2 \right) \left(\frac{d_c}{a} \right)^2 M + \left(\frac{d_c}{a} \right)^4 M = \left(\frac{d_c}{a} \right)^2 M \theta \quad \text{for all } t \geq T_2,$$

where $\theta \equiv [1 + (d_c/a)^2]/2 < 1$. Consequently, we have found $T_2 > 0$ and we have proved the inequalities

$$u(x, t) \leq \frac{d_c}{a} M \left(1 + \frac{d_c}{a} \right) \quad \text{and} \quad v(x, t) \leq \left(\frac{d_c}{a} \right)^2 M \theta \quad \text{for all } t \geq T_2,$$

which correspond to (4.9) when $n = 1$.

Step 2. Now, we assume that (4.9) holds true for $n \in \mathbb{N}$ and we prove it for $n + 1$. Equation (2.1) together with the inductive hypothesis for $v(x, t)$ lead to

$$(4.15) \quad u_t \leq a v(x, t) - d_c u(x, t) \leq a \theta^n \left(\frac{d_c}{a} \right)^2 M - d_c u(x, t) \quad \text{for all } t \geq T_{2n}.$$

Integrating the differential inequality (4.15) for $t \geq T_{2k}$, we obtain

$$\begin{aligned}
 (4.16) \quad u(x, t) &\leq e^{-d_c(t-T_{2n})} u(x, T_{2n}) + \frac{a}{d_c} \theta^n \left(\frac{d_c}{a} \right)^2 M (1 - e^{-d_c(t-T_{2n})}) \\
 &\leq e^{-d_c(t-T_{2n})} \theta^{n-1} \frac{d_c}{a} \left(1 + \frac{d_c}{a} \right) M \\
 &\quad + \frac{a}{d_c} \theta^n \left(\frac{d_c}{a} \right)^2 M (1 - e^{-d_c(t-T_{2n})}) \quad \text{for all } t \geq T_{2n}.
 \end{aligned}$$

Now, we choose $T_{2n+1} > T_{2n}$ in such a way that the following inequality holds

$$e^{-d_c(t-T_{2n})} \theta^{n-1} \frac{d_c}{a} \left(1 + \frac{d_c}{a} \right) M \leq \left(\frac{d_c}{a} \theta^n \right)^2 M \quad \text{for all } t \geq T_{2n+1},$$

which is equivalent to the following one

$$e^{-d_c(t-T_{2n})} (1 + (d_c/a)) \leq (d_c/a) \theta^{n+1} \quad \text{for all } t \geq T_{2n}.$$

Hence, for $t \geq T_{2n+1}$ we obtain from (4.16) that

$$(4.17) \quad u(x, t) \leq \left(\frac{d_c}{a} \theta^n \right)^2 M + \theta^n \frac{d_c}{a} M = \frac{d_c}{a} M \theta^n \left(1 + \frac{d_c}{a} \right) \frac{1 + \frac{d_c}{a} \theta^n}{1 + \frac{d_c}{a}}.$$

Since $(1 + (d_c/a)\theta^n)/(1 + (d_c/a)) < 1$, we have

$$(4.18) \quad u(x, t) \leq \frac{d_c}{a} M \theta^n \left(1 + \frac{d_c}{a} \right) \quad \text{for all } t \geq T_{2n+1}.$$

Next, integrating equation (2.1) and using (4.18), we obtain that the function $v(x, t)$ satisfies for $t \geq T_{2n+1}$ the following inequality

$$\begin{aligned}
 (4.19) \quad v(x, t) &\leq e^{-(d_b+d)(t-T_{2n+1})} v(x, T_{2n+1}) \\
 &\quad + \frac{\left(\frac{d_c}{a} M \theta^n \left(1 + \frac{d_c}{a} \right) \right)^2 K_w}{d_b + d} (1 - e^{-(d_b+d)(t-T_{2n+1})}).
 \end{aligned}$$

It follows from the assumption (2.17) that

$$\frac{\left[\frac{d_c}{a} M \theta^n \left(1 + \frac{d_c}{a} \right) \right]^2 K_w}{d_b + d} \leq \left(\frac{d_c}{a} \right)^4 M \theta^{2n}$$

and from the inductive hypothesis (4.9) that $v(x, T_{2n+1}) \leq \theta^n (d_c/a)^2 M$. Hence, choosing $T_{2(n+1)} > T_{2n+1}$ in such a way that

$$e^{-(d_b+d)(t-T_{2n+1})} \theta^n \left(\frac{d_c}{a} \right)^2 M \leq \frac{1}{2} \left[\left(\frac{d_c}{a} \right)^2 \theta^n M - \left(\frac{d_c}{a} \right)^4 \theta^{2n} M \right] \quad \text{for all } t \geq T_{2(n+1)}$$

or equivalently that

$$e^{-(d_b+d)(t-T_{2n+1})} \leq \frac{1}{2} \left(1 - \left(\frac{d_c}{a} \right)^2 \theta^n \right) \quad \text{for all } t \geq T_{2(n+1)},$$

we deduce from (4.19) that

$$(4.20) \quad v(x, t) \leq \frac{1}{2} \left(\frac{d_c}{a} \right)^2 \theta^n M \left(1 + \left(\frac{d_c}{a} \right)^2 \theta^n \right) \quad \text{for all } t \geq T_{2(n+1)}.$$

Since $[1 + (d_c/a)^2\theta^n]/2 < \theta$, inequality (4.20) implies

$$(4.21) \quad v(x, t) \leq \left(\frac{d_c}{a}\right)^2 M\theta^{n+1} \quad \text{for all } t \geq T_{2(n+1)}.$$

Consequently, inequalities (4.18) and (4.21) hold true for all $t \geq T_{2(n+1)}$ and the proof of the inductive step is complete. $\square$

Proof of Corollary 2.4. It follows immediately from Theorem 2.2 that $u(x, t) \rightarrow 0$ and $v(x, t) \rightarrow 0$ as $t \rightarrow \infty$ uniformly in $x \in [0, 1]$. To show that $\|w(t) - \kappa_0/d_g\|_\infty \rightarrow 0$ as $t \rightarrow \infty$ we use the fundamental solution $B(x, y, t)$ of the equation $Z_t = \gamma^{-1}Z_{xx} - d_g Z$ for $x \in (0, 1)$ and $t > 0$, supplemented with the Neumann boundary condition. Noting (3.14) and the positivity of all functions in the integral representation of w from (3.16) we obtain the inequality (c.f. (3.17))

$$(4.22) \quad \|w(t) - \kappa_0/d_g\|_\infty \leq \|w_0 - \kappa_0/d_g\|_\infty e^{-d_g t} + d \int_0^t \int_0^1 B(x, y, t-s) v(y, s) dy ds.$$

Since $v(x, t) \leq (d_c/a)^2 M$ for all $x \in [0, 1]$ and $t > 0$ by Lemma 4.3, we see

$$\int_0^{t/2} \int_0^1 B(x, y, t-s) v(y, s) dy ds \leq \left(\frac{d_c}{a}\right)^2 M \int_0^{t/2} e^{-d_g(t-s)} ds \rightarrow 0 \quad \text{as } t \rightarrow \infty.$$

On the other hand,

$$\int_{t/2}^t \int_0^1 B(x, y, t-s) v(y, s) dy ds \leq \left(\sup_{s \in [t/2, t]} v(x, s) \right) \frac{1}{d_g} (1 - e^{-d_g t/2}).$$

It follows from Theorem 2.2 that the right-hand side above tends to 0 as $t \rightarrow \infty$. Consequently, we conclude from (4.22) that $\|w(t) - \kappa_0/d_g\|_\infty \rightarrow 0$ as $t \rightarrow \infty$. $\square$

5. CONSTRUCTION OF PATTERNS

In this section, we discuss stationary solutions of system (2.1)-(2.4) (or equivalently of system (2.19)-(2.22)). First, we limit ourselves to nonzero $U(x)$ and $V(x)$ to obtain relations (2.23) as well as the boundary value problem (2.24)-(2.25).

Let us begin with an arbitrary C^1 -function $h : (0, \infty) \rightarrow \mathbb{R}$. By the change of variables

$$(5.1) \quad x \mapsto Tx, \quad \text{where } T = \sqrt{\gamma},$$

one can transform the boundary value problem

$$\frac{1}{\gamma} w'' + h(w) = 0, \quad w'(0) = w'(1) = 0, \quad \text{with } x \in (0, 1),$$

into the problem

$$(5.2) \quad w'' + h(w) = 0, \quad x \in (0, T),$$

$$(5.3) \quad w'(0) = w'(T) = 0.$$

Together with equation (5.2), we consider the corresponding system of the first order equations

$$(5.4) \quad w' = z, \quad z' = -h(w).$$

Hence, solutions of equation (5.2) satisfying the boundary conditions (5.3) correspond to trajectories of system (5.4) satisfying $z(0) = z(T)$ for a certain $T > 0$. Here, we should recall that system (5.4) is autonomous in the following sense: if $(w(x), z(x))$ is a solution, then $(w(x + x_0), z(x + x_0))$ is a solution for all $x_0 \in \mathbb{R}$, as well.

FIGURE 5.1. The graph of the potential energy $H = H(w)$ defined in (5.6) and the closed trajectory of system (5.4) with the energy level $E > 0$.

Multiplying second equation in (5.4) by $z = z(x)$ and using first one, we obtain the equation for all trajectories of system (5.4)

$$(5.5) \quad \frac{z^2}{2} + H(w) = E,$$

where $H' = h$ and $E \in \mathbb{R}$ is an arbitrary constant. Recall that the constant E is called the *total energy* in the classical mechanics, the function H corresponds to the *potential energy*, and relation (5.5) is the *first integral* of system (5.4).

It follows from equation (5.5) that all trajectories of system (5.4) are symmetric with respect to the w -axis. Hence, the condition $z(0) = w'(0) = z(T) = w'(T)$ is satisfied for a certain $T > 0$ if equation (5.5) describes a closed curve on the wz -plane for a some $E \in \mathbb{R}$. Such closed curves exist only if the potential energy $H = H(w)$ has a local minimum at a certain point $\bar{w}_-$, see Fig. 5.1.

Let us apply these classical ideas to obtain preliminary results on the nonexistence of stationary solutions of system (2.19)-(2.22). Now, the function h is defined in (2.26).

Proposition 5.1. *Assume that $a \leq d_c$, $\gamma > 0$, and d, d_b, d_g, κ_0 be arbitrary and positive. Then, the only nonnegative solution of system (2.19)-(2.22) is the trivial steady state $(0, 0, \kappa_0/d_g)$.*

Proof. If $a < d_c$, the nonexistence of stationary solutions, except the trivial one, is guaranteed by Proposition 4.1.

For $a = d_c$, it follows from equation (2.19) that $U \equiv 0$ and, by equation (2.20), we obtain $V \equiv 0$. Consequently, using (2.21) we obtain the following boundary value problem for

the function $W = W(x)$

$$\begin{aligned} \frac{1}{\gamma} W_{xx} - d_g W + \kappa_0 &= 0, \quad x \in (0, 1) \\ W_x(0) &= W_x(1) = 0. \end{aligned}$$

Here, the potential energy $H(w) = -d_g w^2/2 + \kappa_0 w$ has no local minimum and the corresponding equation for trajectories (5.5) does not describe any closed curve, except $E = H(\kappa_0/d_g)$ and the stationary point $(w, z) = (\kappa_0/d_g, 0)$. $\square$

In the following proposition, we discuss the nonexistence of positive solutions of the boundary value problem (2.24)-(2.25).

Proposition 5.2. *Assume that $a > d_c$ and $\gamma > 0$. Let other constants in (2.24) be nonnegative and arbitrary.*

- i. *If $\kappa_0^2 < \Theta$ (cf. (2.11)), then the boundary value problem (2.24)-(2.25) has no positive solutions.*
- ii. *If $\kappa_0^2 = \Theta$, then the constant function $w \equiv \kappa_0/d_g$ is the only solution of the boundary value problem (2.24)-(2.25).*

Proof. Direct calculations (see Appendix A – a discussion around equation (A.7)) show that, under the assumption $\kappa_0^2 < \Theta$, the function h defined in (2.26) satisfies $h(w) = H'(w) < 0$ for all $w > 0$. Hence, the associated potential energy H , (see formula (5.6), below) is strictly decreasing and, in consequence, equation (5.5) does not define any closed trajectory of system (5.4).

If $\kappa_0^2 = \Theta$, the function H is decreasing, as well. Here, however, system (5.4) has a stationary point $(\kappa_0/(2d_g), 0)$. $\square$

Hence, in view of Propositions 5.1 and 5.2, we have to assume that $a > d_c$ and $\kappa_0^2 > \Theta$ to be able to construct nonconstant stationary solutions of the boundary value problem (2.24)-(2.25). It follows from direct calculations (see the beginning of Appendix) that, under these assumptions, the numbers $\bar{w}_\pm$ from (2.12) are the only positive zeros of the function h defined in (2.26). Moreover, the corresponding potential energy (namely, $H' = h$)

$$(5.6) \quad H(w) = -d_g w^2/2 - d_b \frac{d_c^2(d_b + d)}{(a - d_c)^2} \log w + \kappa_0 w$$

has a local minimum in $\bar{w}_-$, a local maximum in $\bar{w}_+$.

To describe inhomogeneous stationary solutions, let us come back to the abstract boundary value problem (5.2)-(5.3) and recall how to calculate the number $T > 0$ such that $w'(0) = w'(T) = 0$. Indeed, in view of equation (5.5), every solution $w = w(x)$ to problem (5.2)-(5.3) satisfies the first order differential equation

$$(5.7) \quad w'(x) = \pm \sqrt{2(E - H(w(x)))}.$$

Hence, choosing the upper branch in (5.7) and integrating with respect to x we obtain

$$T = \int_0^T \frac{w'(x) dx}{\sqrt{2(E - H(w(x)))}}.$$

Next, let us introduce $w_{1,E} < w_{2,E}$ such that $w_{1,E} = w(0)$ and $w_{2,E} = w(T)$, hence $H(w_{1,E}) = H(w_{2,E}) = E$, see Fig. 5.1. Since $w = w(x)$ is nondecreasing for $x \in [0, T]$,

by the change of variables $y = w(x)$ we obtain the following formula for T as a function of E :

$$(5.8) \quad T = T(E) = \int_{w_{1,E}}^{w_{2,E}} \frac{dy}{\sqrt{2(E - H(y))}}.$$

Our classification of all nonnegative solutions of the boundary value problem (5.2)-(5.3) is based on detailed analysis of the integral (5.8), which properties are stated in the following lemmas.

Lemma 5.3. *Assume $H \in C^2(0, \infty)$ has a local minimum at $\bar{w}_-$ such that $H''(\bar{w}_-) > 0$. We consider every $E > H(\bar{w}_-)$ such that there exist $w_{1,E}$ and $w_{2,E}$ with the following properties (see Fig. 5.1):*

- $H(w_{1,E}) = H(w_{2,E}) = E$, $H'(w_{1,E}) \neq 0$, $H'(w_{2,E}) \neq 0$,
- $w_{1,E} < \bar{w}_- < w_{2,E}$,
- $H(w) < E$ for all $w \in (w_{1,E}, w_{2,E})$.

Then, for all such constants E the integral $T(E)$ defined in (5.8) is convergent and depends continuously on E . Moreover, $\lim_{E \searrow H(\bar{w}_-)} T(E) = \pi / \sqrt{H''(\bar{w}_-)}$.

Proof. By the assumptions on the function H , the integrand of $T(E)$ from (5.8) has singularities at $w_{1,E}$ and $w_{2,E}$, only. Thus, the integral $T(E)$ is convergent by the Taylor expansion, because $H'(w_{1,E}) \neq 0$ and $H'(w_{2,E}) \neq 0$. To show the continuous dependence of $T(E)$ on E , it suffices to apply *e.g.* the Lebesgue dominated convergence theorem.

To calculate the limit $\lim_{E \rightarrow H(\bar{w}_-)} T(E)$, first, we recall that $E = H(w_{2,E})$ and we consider the integral

$$T_1(E) \equiv \int_{\bar{w}_-}^{w_{2,E}} \frac{dy}{\sqrt{2(H(w_{2,E}) - H(y))}} = \int_0^{w_{2,E} - \bar{w}_-} \frac{dy}{\sqrt{2(H(w_{2,E}) - H(y + \bar{w}_-))}}.$$

Defining the new parameter $s = w_{2,E} - \bar{w}_-$ and the shifted function $\bar{H}(w) \equiv H(y + \bar{w}_-)$, moreover, changing variables we obtain

$$(5.9) \quad \lim_{E \rightarrow H(\bar{w}_-)} T_1(E) = \lim_{s \rightarrow 0} \int_0^s \frac{dy}{\sqrt{2(\bar{H}(s) - \bar{H}(y))}} = \lim_{s \rightarrow 0} \int_0^1 \frac{dy}{\sqrt{2s^{-2}(\bar{H}(s) - \bar{H}(sy))}}.$$

Consequently, we apply the Lebesgue dominated convergence theorem combined with the l'Hospital rule to the integral on the right-hand side of (5.9) to show

$$\lim_{E \rightarrow H(\bar{w}_-)} T_1(E) = \frac{1}{\sqrt{\bar{H}''(0)}} \int_0^1 \frac{dy}{\sqrt{1 - y^2}}.$$

Now, it suffices to recall that $\bar{H}''(0) = H''(\bar{w}_-)$.

In a completely analogous way, one calculates the limit

$$\lim_{E \rightarrow H(\bar{w}_-)} \int_{w_{1,E}}^{\bar{w}_-} \frac{dy}{\sqrt{2(E - H(y))}} = \frac{1}{\sqrt{H''(\bar{w}_-)}} \int_{-1}^0 \frac{dy}{\sqrt{1 - y^2}}$$

and the proof is complete because $\int_{-1}^1 1/\sqrt{1 - y^2} dy = \pi$. $\square$

Lemma 5.4. *Assume that $H \in C^2(0, \infty)$ has, for certain $0 < \bar{w}_- < \bar{w}_+$, the following properties*

- H is strictly decreasing on $(0, \bar{w}_-)$ and strictly increasing on $(\bar{w}_-, \bar{w}_+)$;
- $H'(\bar{w}_+) = 0$.

For every $E \in (H(\bar{w}_-), H(\bar{w}_+))$, choose $w_{1,E} < \bar{w}_- < w_{2,E} < \bar{w}_+$ such that $H(w_{1,E}) = H(w_{2,E}) = E$, see Fig. 5.1. Then $\lim_{E \nearrow H(\bar{w}_+)} T(E) = +\infty$.

Proof. It suffices to show that

$$\lim_{E \nearrow H(\bar{w}_+)} \int_{\bar{w}_-}^{w_{2,E}} \frac{dy}{\sqrt{2(H(w_{2,E}) - H(y))}} = +\infty.$$

The function H is increasing on $(\bar{w}_-, \bar{w}_+)$ and $H'(\bar{w}_+) = 0$, hence, by the Taylor expansion, we obtain

$$H(w_{2,E}) - H(y) \leq H(\bar{w}_+) - H(y) \leq \frac{\tilde{m}}{2}(\bar{w}_+ - y)^2 \quad \text{with} \quad \tilde{m} = \sup_{y \in (\bar{w}_-, \bar{w}_+)} |H''(y)|$$

for all $y \in (\bar{w}_-, w_{2,E})$. Consequently,

$$\int_{\bar{w}_-}^{w_{2,E}} \frac{dy}{\sqrt{2(H(w_{2,E}) - H(y))}} \geq \frac{1}{\sqrt{\tilde{m}}} \int_{\bar{w}_-}^{w_{2,E}} \frac{dy}{\bar{w}_+ - y} \rightarrow +\infty \quad \text{if} \quad w_{2,E} \rightarrow \bar{w}_+.$$

□

Lemma 5.5. Assume that a function H has all properties stated in Lemma 5.4. Suppose, moreover, that $H \in C^3(0, \infty)$, $h = H'$ satisfies $h''(w) \leq 0$ for every $w \in (0, \bar{w}_+)$, h'' is not constant on any interval, and $h(\bar{w}_-) = H'(\bar{w}_-) = 0$. Then $T(E)$ defined in (5.8) is a strictly increasing function of $E \in (H(\bar{w}_-), H(\bar{w}_+))$.

Proof. Obviously, it suffices to show that $dT(E)/dE > 0$ using the explicit formula (5.8). These involved calculations were done by Loud [4] by using a clever change of variables. Let us recall that result in our particular case.

First, we consider the integral

$$(5.10) \quad T_1(E) = \int_{\bar{w}_-}^{w_{2,E}} \frac{dy}{\sqrt{2(H(w_{2,E}) - H(y))}},$$

where shifting the variable y as in the proof of Lemma 5.3, we can assume that $\bar{w}_- = 0$, without loss of generality. Since H is strictly increasing on $(0, \bar{w}_+)$, denoting $H(A) = E$, it suffices to show that the following function of A

$$\tilde{T}(A) \equiv T_1(H(A)) = \int_0^A \frac{dy}{\sqrt{2(H(A) - H(y))}}$$

is strictly increasing. It is calculated in [4, Thm. 1, Eq. (2.5)] that

$$(5.11) \quad \frac{d\tilde{T}(A)}{dA} = -\sqrt{2} \frac{h(A)}{H(A)} \int_0^A \left[\frac{H(y)h'(y)}{h(y)^2} - \frac{1}{2} \right] \frac{dy}{\sqrt{2(H(A) - H(y))}}.$$

Now, we denote by $f(y)$ the quantity in the brackets on the right hand side of (5.11) and we observe that, for every $y \in [0, A]$, we have

$$(5.12) \quad \frac{d}{dy}(h^2(y)f(y)) = H(y)h''(y) \quad \text{and} \quad h^2(0)f(0) = 0.$$

By the assumptions, $H(y) \geq 0$ and $h''(y) \leq 0$. Therefore, it follows from (5.12) that $h^2(y)f(y) \leq 0$ and, in consequence, $f(y) \leq 0$ for all $y \in [0, A]$. Finally, the right-hand side of equation (5.11) is positive because $h(A) \geq 0$ and $H(A) \geq 0$.

The analysis is completely analogous in the case of the counterpart of the integral $T_1(E)$, where we integrate with respect to $y \in [w_{1,E}, \bar{w}_-]$. □

Now, we come back to boundary-value problem (2.24)-(2.25) with the function h defined in (2.26), and with the corresponding potential energy H from (5.6).

Theorem 5.6. *Assume that $a > d_c$, $\kappa_0^2 > \Theta$, and $\gamma \in (0, \gamma_0]$, where γ_0 is defined in (2.27). Then, the constant steady states $\bar{w}_\pm$ (cf. (2.12)) are the only solutions of the boundary value problem (2.24)-(2.25).*

Proof. Recall that every non-constant solution $w = w(x)$ of problem (2.24)-(2.25) corresponds to a non-constant trajectory $(w(x), z(x))$ of system (5.4) such that $z(0) = z(T) = 0$ with $T = \sqrt{\gamma}$. However, by Lemmas 5.3 and 5.5, such trajectories exist only if $T > \pi/\sqrt{H''(\bar{w}_-)} = \sqrt{\gamma_0}$. $\square$

Now, we prove our main result on the existence of continuous and positive stationary solutions of system (2.1)-(2.4). First, we notice that, if $W = W(x)$ is a solution of problem (2.24)-(2.25), then so is $\widetilde{W}(x) = W(1 - x)$. More generally, for every $A, B \in \mathbb{R}$, the function $\widehat{W}(x) \equiv W(Ax - B)$ is a solution of equation (2.24) with γ replaced by $A^2\gamma$, satisfying the boundary conditions $\widehat{W}_x(B/A) = \widehat{W}_x((T + B)/A) = 0$.

Proof of Theorem 2.6. The potential energy $H = H(w)$ associated with equation (2.24) has the form (5.6) and, under the assumption $\kappa_0^2 > \Theta$, it has a local minimum in $\bar{w}_-$, a local maximum in $\bar{w}_+$, and all properties required in Lemmas 5.3–5.5. Obviously, the numbers $\bar{w}_\pm$ are constant solutions of the boundary value problem (2.24)-(2.25).

For every $E \in (H(\bar{w}_-), H(\bar{w}_+))$, let us consider the trajectory $(w(x), z(x))$ of system (5.4) such that $z \geq 0$ and $z(0) = z(T) = 0$ (namely, the upper half of the trajectory drawn in Fig. 5.1). Here, $T = T(E)$ is defined by the integral (5.8) and, by Lemmas 5.3–5.5, this is a continuous and increasing function of E , which takes all values from the half-line $(\pi/\sqrt{H''(\bar{w}_-)}, \infty)$. Due to the change of variables (5.1), the function $W(x) = w(x/T)$ is the unique increasing solution of the boundary value problem (2.24)-(2.25) with $\gamma = T^2$. On the other hand, the lower half of the trajectory drawn in Fig. 5.1, more precisely, the function $\widetilde{W}(x) = W(1 - x)$, is the unique decreasing solution of (2.24)-(2.25).

Now, for fixed $\gamma > \gamma_0$, let us choose the biggest $n \in \mathbb{N}$ such that $\gamma/n^2 > \gamma_0$ and suppose that $n \geq 2$. For each $k \in \{2, \dots, n\}$, we consider the unique trajectory $(w_k(x), z_k(x))$ of system (5.4) such that $z_k(x) \geq 0$ and $z_k(0) = z_k(T_k) = 0$ with $T_k = \sqrt{\gamma}/k$. Hence, $W_k(x) = w_k(x/(kT_k))$ for $x \in (0, kT_k)$ is the solution with k modes of the boundary value problem (2.24)-(2.25). Another solutions with k modes is the symmetric counterpart $\widetilde{W}_k(x) = W_k(1 - x)$.

These are all solutions and there exists no other solutions, because $T = T(E)$ is a continuous and strictly increasing function of E , see Lemmas 5.3–5.5. Hence, we obtain all trajectories $(w(x), z(x))$ of system (5.4) such that $z(0) = z(T)$ for each $T > \pi/\sqrt{H''(\bar{w}_-)}$. $\square$

Proof of Theorem 2.9. First, we change variables as in (5.1), hence, we consider weak solutions of system (2.19)-(2.22) (with $1/\gamma = 1$) on the interval $[0, T]$ (with $T = \sqrt{\gamma}$). In these new variables, if $U(x) = V(x) = 0$ for some $x \in (0, T)$, the function W satisfies the equation

$$W''(x) - d_g W(x) + \kappa_0 = 0.$$

Trajectories of the corresponding system on the WZ -plane

$$(5.13) \quad W' = Z, \quad Z' = d_g W - \kappa_0$$

FIGURE 5.2. Two closed trajectories of system (5.4) with energy levels $E_1 > 0$. Three trajectories of system (5.13) with energy levels $E_2 > 0$. The bold line shows a trajectory corresponding to a discontinuous pattern.

are unbounded and have the following explicit form $Z = \pm\sqrt{2E_2 + d_g W^2 - 2\kappa_0 W}$ for every constant $E_2 > 0$, see Fig. 5.2.

On the other hand, if $U(x) \neq 0$ and $V(x) \neq 0$ for some $x \in (0, T)$, we use relations (2.23) for $U(x), V(x)$ together with equation (2.24) for $W(x)$ as well as the corresponding system on the WZ -plane (5.4) with h defined in (2.26). Recall that, under our assumptions, this system has closed trajectories described by the formula (5.5), see Fig. 5.1.

Now, we construct a continuous trajectory (W, Z) , which corresponds to a weak solution of (2.19)-(2.22) in the following way. We begin at the W -axis at $x = 0$ and finishing at the W -axis as a certain $T > 0$ going along either trajectories of system (5.13) or trajectories of system (5.4). At each point of the intersection of two trajectories of different types, the function W is C^1 because $Z = W'$ is continuous. Fig. 5.2 shows examples of such trajectories.

One can easily check that the constructed-in-this-way function $W = W(x)$ satisfies the integral equation (2.29) for every test function $\varphi \in C^1([0, 1])$. $\square$

6. LINEARIZATION AND SPECTRAL ANALYSIS

In this section, we show instability of stationary solutions of system (2.1)-(2.5), which are constructed either in Theorems 2.6 or in 2.9. Writing equations (2.1)-(2.3) in the form

$$(6.1) \quad u_t = f_1(u, v), \quad v_t = f_2(u, v, w), \quad w_t = \frac{1}{\gamma} w_{xx} + f_3(u, v, w),$$

we obtain that the differential of the mapping $F = (f_1, f_2, f_3) : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ satisfies

$$(6.2) \quad DF(u, v, w) = \begin{pmatrix} \frac{av^2}{(u+v)^2} - d_c & \frac{au^2}{(u+v)^2} & 0 \\ 2uw & -d_b - d & u^2 \\ -2uw & d & -d_g - u^2 \end{pmatrix}.$$

Assume first that $U(x) > 0$ and $V(x) > 0$ for some $x \in (0, 1)$. Using relations (2.23), we obtain the equalities

$$\frac{V(x)^2}{(U(x) + V(x))^2} = \frac{d_c^2}{a^2} \quad \text{and} \quad \frac{U(x)^2}{(U(x) + V(x))^2} = \frac{(a - d_c)^2}{a^2}.$$

Hence,

$$(6.3) \quad DF(U, V, W) = \mathcal{A}(x) = (a_{ij})_{i,j=1,2,3} \equiv \begin{pmatrix} -\frac{d_c(a-d_c)}{a} & \frac{(a-d_c)^2}{a} & 0 \\ 2K & -d_b - d & \frac{K^2}{W^2(x)} \\ -2K & d & -d_g - \frac{K^2}{W^2(x)} \end{pmatrix},$$

with the constant

$$K = U(x)W(x) = \frac{d_c(d_b + d)}{a - d_c},$$

see (2.23). Notice that only the coefficients a_{23} and a_{33} depend on x .

Hence, the linearization of problem (2.1)-(2.5) at a continuous steady state (U, V, W) (namely, when $U(x) > 0$ and $V(x) > 0$ for all $x \in [0, 1]$) contains the linear operator

$$(6.4) \quad \mathcal{L} \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \frac{1}{\gamma} \partial_x^2 \eta \end{pmatrix} + \mathcal{A} \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix},$$

and we consider it as an operator in the Hilbert space $\mathcal{H}$ with the domain $D(\mathcal{L})$, where

$$(6.5) \quad \mathcal{H} = L^2(0, 1) \times L^2(0, 1) \times L^2(0, 1) \quad \text{and} \quad D(\mathcal{L}) = L^2(0, 1) \times L^2(0, 1) \times W^{2,2}(0, 1).$$

First, we prove two lemmas which allow us to characterize the point spectrum of the operator $\mathcal{L}$. Here, we do not use any particular form of the coefficients in the matrix $\mathcal{A}$ in (6.3). Below, we denote by $\mathcal{A}_{12}$ the matrix obtained from $\mathcal{A}$ after removing the third row and the third column, namely,

$$(6.6) \quad \mathcal{A}_{12} \equiv \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}.$$

Lemma 6.1. *Assume that the matrix $\mathcal{A}_{12}$ has constant coefficients and let λ_0 be its eigenvalue. Then λ_0 belongs to the continuous spectrum of the operator $\mathcal{L}$ defined in (6.4).*

Proof. Let us first show that λ_0 is not an eigenvalue of the operator $\mathcal{L}$. To do it, we should show that $(\varphi, \psi, \eta) = (0, 0, 0)$ is the only solution of the system

$$(6.7) \quad \begin{aligned} (a_{11} - \lambda_0)\varphi + a_{12}\psi &= 0, \\ a_{21}\varphi + (a_{22} - \lambda_0)\psi + a_{23}\eta &= 0, \\ \frac{1}{\gamma}\eta'' + a_{31}\varphi + a_{32}\psi + (a_{33} - \lambda_0)\eta &= 0, \\ \eta'(0) = \eta'(1) &= 0. \end{aligned}$$

Since λ_0 is an eigenvalue of the matrix $\mathcal{A}_{12}$, the vectors $(a_{11} - \lambda_0, a_{12})$ and $(a_{21}, a_{22} - \lambda_0)$ are linearly dependent, namely, there is $r_1 \in \mathbb{R}$ such that

$$(6.8) \quad (a_{11} - \lambda_0, a_{12}) = r_1(a_{21}, a_{22} - \lambda_0).$$

Hence, it follows from the first and the second equation in (6.7) that $\eta \equiv 0$ and there exists a number r (in fact, $r = -a_{12}/(a_{11} - \lambda_0)$) such that $\varphi = r\psi$. We substitute this relation into the third equation in (6.7) to obtain the equality $(ra_{31} + a_{32})\psi = 0$ that implies $\psi \equiv 0$ and, consequently, $\varphi \equiv 0$.

Thus, we have proved that the operator $\mathcal{L} - \lambda_0 I : D(\mathcal{L}) \rightarrow \mathcal{H}$ (cf. (6.5)) is invertible. However, its inverse cannot be continuous, because $(\mathcal{L} - \lambda_0 I)^{-1}$ is not defined on the whole space $\mathcal{H}$. Indeed, using relation (6.8) in the first and the second equation in (6.7), we obtain the equality $r_1 a_{23} \eta = r_1 g - f$. Hence,

$$(6.9) \quad (r_1 g - f)/(r_1 a_{23}) \in W^{2,2}(0, 1)$$

is a necessary condition for system (6.7) to have a solution $(\varphi, \psi, \eta) \in D(\mathcal{L})$. Obviously, the condition in (6.9) is not satisfied for every $f, g \in L^2(0, 1)$. This completes the proof of Lemma 6.1. $\square$

Lemma 6.2. *A complex number λ is an eigenvalue of the operator $\mathcal{L}$ if and only if the following two conditions are satisfied*

- λ is not an eigenvalue of the matrix $\mathcal{A}_{12}$,
- the boundary value problem

$$(6.10) \quad \begin{aligned} \frac{1}{\gamma}\eta'' + \frac{\det(\mathcal{A} - \lambda I)}{\det(\mathcal{A}_{12} - \lambda I)}\eta &= 0, \quad x \in (0, 1) \\ \eta'(0) &= \eta'(1) = 0 \end{aligned}$$

has a nontrivial solution.

Proof. Assume that the number $\lambda \in \mathbb{C}$ is an eigenvalue of the operator $\mathcal{L}$. Hence, the system

$$(6.11) \quad \begin{aligned} (a_{11} - \lambda)\varphi + a_{12}\psi &= 0 \\ a_{21}\varphi + (a_{22} - \lambda)\psi + a_{23}\eta &= 0 \\ \frac{1}{\gamma}\eta'' + a_{31}\varphi + a_{32}\psi + (a_{33} - \lambda)\eta &= 0, \end{aligned}$$

supplemented with the boundary condition $\eta'(0) = \eta'(1) = 0$, has a non-zero solution $(\varphi_0, \psi_0, \eta_0)$. By Lemma 6.1, λ is not an eigenvalue of the matrix $\mathcal{A}_{12}$. Hence, $\det(\mathcal{A}_{12} - \lambda I) \neq 0$ and from the first and the second equation in (6.11) we obtain

$$(6.12) \quad \varphi = \frac{a_{12}a_{23}}{\det(\mathcal{A}_{12} - \lambda I)}\eta \quad \text{and} \quad \psi = -\frac{(a_{11} - \lambda)a_{23}}{\det(\mathcal{A}_{12} - \lambda I)}\eta.$$

Substituting these identities to the third equation in (6.11) provides the relation

$$(6.13) \quad \frac{1}{\gamma}\eta'' + \frac{a_{31}a_{12}a_{23} - a_{32}(a_{11} - \lambda)a_{23} + (a_{33} - \lambda)\det(\mathcal{A}_{12} - \lambda I)}{\det(\mathcal{A}_{12} - \lambda I)}\eta = 0,$$

which reduces to the equation in (6.10), because the quantity $a_{31}a_{12}a_{23} - a_{32}(a_{11} - \lambda)a_{23} + (a_{33} - \lambda)\det(\mathcal{A}_{12} - \lambda I)$ is the Laplace expansion of the determinant $\det(\mathcal{A} - \lambda I)$ with respect to its third column.

Now, let us prove the reverse implication. Assume that $\lambda \in \mathbb{C}$ is not an eigenvalue of $\mathcal{A}_{12}$ and denote by η a non-zero solution of problem (6.10). Hence, the vector (φ, ψ, η) , where φ and ψ are defined in (6.12), is the eigenvector of the operator $\mathcal{L}$ corresponding to the eigenvalue λ . $\square$

We are now in a position to show the existence of an infinite sequence of positive eigenvalues of the operator $\mathcal{L}$ and to prove Theorem 2.10. First, we consider the simplest case of the constant stationary solution $(U(x), V(x), W(x)) = (\bar{u}_-, \bar{v}_-, \bar{w}_-)$. Here, we need a simple technical lemma.

Lemma 6.3. *Assume that a 3×3 -matrix $\mathcal{A}$ with real coefficients has all 3 eigenvalues with negative real parts. Then, its characteristic polynomial satisfies $\det(\mathcal{A} - \lambda I) < 0$ for all $\lambda \geq 0$.*

Proof. Since the polynomial $\det(\mathcal{A} - \lambda I)$ has real coefficients, it has three roots $\lambda_1, \lambda_2, \lambda_3 \in \mathbb{C}$ satisfying $\lambda_1 \in \mathbb{R}$ and $\lambda_3 = \bar{\lambda}_2$. Hence,

$$\det(\mathcal{A} - \lambda I) = -(\lambda - \lambda_1)(\lambda - \lambda_2)(\lambda - \bar{\lambda}_2) = -(\lambda - \lambda_1)(|\lambda_2|^2 - 2\lambda \operatorname{Re} \lambda_2 + \lambda^2).$$

The factor $(\lambda - \lambda_1)$ is positive for all $\lambda \geq 0$, because $\lambda_1 < 0$ by the assumption. The last factor on the right-hand side is positive for every $\lambda > 0$, because $\operatorname{Re} \lambda_2 < 0$. $\square$

Theorem 6.4 (Instability of the constant steady state). *Denote by λ_0 the positive eigenvalue of the matrix $\mathcal{A}_{12}$. Consider the operator $\mathcal{L}$ from (6.4) with the constant coefficient matrix $\mathcal{A}$ obtained from the constant steady state $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$. Then, there exists a sequence $\{\lambda_n\}_{n \in \mathbb{N}}$ of positive eigenvalues of the operator $\mathcal{L}$ that satisfy $\lambda_n \rightarrow \lambda_0$ as $n \rightarrow \infty$.*

Proof. In view of Lemma 6.2, we look for an infinite sequence of numbers λ_n such the boundary value problem (6.10) has a nontrivial solution. First, recall that the following eigenvalue value problem on the interval $[0, 1]$

$$(6.14) \quad \frac{1}{\gamma} \eta'' + \mu \eta = 0, \quad \eta'(0) = \eta'(1) = 0$$

has a nonzero solution $\eta(x) = \eta_n(x) = \cos(n\pi x)$ if $\mu = \mu_n = n^2\pi^2/\gamma$ for each $n \in \mathbb{N}$.

By Lemma 6.3, the polynomial $\det(\mathcal{A} - \lambda I)$ is negative for all $\lambda \geq 0$, because the steady state $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$ is a stable solution of the kinetic system (A.1)-(A.3), see Corollary A.10 in Appendix.

Since λ_0 is the only positive eigenvalue of the matrix $\mathcal{A}_{12}$, the quadratic polynomial $\det(\mathcal{A}_{12} - \lambda I)$ has the following properties: $\det(\mathcal{A}_{12} - \lambda I) < 0$ for $\lambda \in [0, \lambda_0)$ and $\det(\mathcal{A}_{12} - \lambda_0 I) = 0$. Hence, $\det(\mathcal{A} - \lambda I)/\det(\mathcal{A}_{12} - \lambda I) > 0$ for all $\lambda \in [0, \lambda_0)$ and the left-hand side limit satisfies

$$\lim_{\lambda \rightarrow \lambda_0^-} \frac{\det(\mathcal{A} - \lambda I)}{\det(\mathcal{A}_{12} - \lambda I)} = +\infty.$$

By continuity, we immediately obtain a sequence $\lambda_n \rightarrow \lambda_0$ such that

$$\frac{\det(\mathcal{A} - \lambda_n I)}{\det(\mathcal{A}_{12} - \lambda_n I)} = \mu_n = \frac{n^2\pi^2}{\gamma}$$

for all sufficiently large $n \in \mathbb{N}$. $\square$

More-or-less similar idea is used to find positive eigenvalues of the operator $\mathcal{L}$ in the case of non-homogeneous steady states. First, however, we recall properties of eigenvalues $\mu \in \mathbb{R}$ of the boundary value problem

$$(6.15) \quad \frac{1}{\gamma} \eta'' + \mu q \eta = 0, \quad \eta'(0) = \eta'(1) = 0,$$

where $q \in L^\infty(0, 1)$ is nonnegative. It is well-known that problem (6.15) has a sequence of eigenvalues $\{\mu_n(q)\}_{n=1}^\infty$ satisfying

$$0 = \mu_0(q) < \mu_1(q) < \mu_2(q) < \mu_3(q) < \cdots \rightarrow +\infty.$$

Moreover, these eigenvalues depend continuously on the potential $q = q(x)$ in the following sense.

Lemma 6.5. *Let $q_1, q_2 \in L^\infty(0, 1)$ be nonnegative and fixed. Denote by $\{\mu_n(q_i)\}_{n=1}^\infty$, $i = 1, 2$, the corresponding eigenvalues of problem (6.15). Then, there exists a constant $C > 0$ such that for all $n \in \mathbb{N}$, it holds*

$$|\mu_n(q_1) - \mu_n(q_2)| \leq \gamma C \|q_1 - q_2\|_{L^2(0,1)}.$$

Moreover, if $q_1(x) \leq q_2(x)$ a.e. then $\mu_n(q_2) \leq \mu_n(q_1)$ for each $n \in \mathbb{N}$.

Proof. Denoting by $G(x, y)$ the Green function of the operator $-d^2/dx^2$ with the Neumann boundary conditions, we convert problem (6.15) into the integral equation

$$\eta(x) = \gamma \mu(q) \int_0^1 G(x, y) q(y) \eta(y) dy, \quad x \in [0, 1],$$

where the right-hand side defines a compact, self-adjoint, nonnegative operator on $L^2(0, 1)$. Hence, properties of eigenvalues, stated in this lemma, result immediately from the abstract theory, see *eg.* [12, Cor. 5.6 and Thm. 5.7]. $\square$

Proof of Theorem 2.10. By Lemma 6.1, the number λ_0 belongs to the continuous spectrum of the operator $\mathcal{L}$. Next, denoting

$$(6.16) \quad q(x, \lambda) = \frac{\det(\mathcal{A}(x) - \lambda I)}{\det(\mathcal{A}_{12} - \lambda I)},$$

we rewrite problem (6.10) in the form

$$(6.17) \quad \frac{1}{\gamma} \eta''(x) + q(x, \lambda) \eta(x) = 0, \quad \eta'(0) = \eta'(1) = 0.$$

By Lemma 6.2, it suffices to find a sequence $\lambda = \lambda_n \rightarrow \lambda_0$ such that problem (6.17) has a nonzero solution. We shall proceed in a sequence of steps.

Step 1. There exists $\varepsilon > 0$ such that for every $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$, we have

$$\min_{x \in [0, 1]} q(x, \lambda) \equiv \omega(\lambda) > 0 \quad \text{and} \quad \omega(\lambda) \rightarrow \infty \quad \text{and} \quad \lambda \rightarrow \lambda_0.$$

To show this property of the potential $q(x, \lambda)$, we use its expanded form from equation (6.13)

$$(6.18) \quad q(x, \lambda) = a_{23}(x) \frac{a_{31}a_{12} - a_{32}(a_{11} - \lambda)}{\det(\mathcal{A}_{12} - \lambda I)} + a_{33}(x) - \lambda,$$

where, by (6.3),

$$(6.19) \quad a_{23} = \frac{K^2}{W^2(x)} \quad \text{and} \quad a_{33}(x) = -d_g - \frac{K^2}{W^2(x)}, \quad \text{with} \quad K = \frac{d_c(d_b + d)}{a - d_c},$$

and other coefficients on the right-hand side are x -independent. Recall (see the proof of Theorem 6.4) that $\det(\mathcal{A}_{12} - \lambda I) < 0$ for $\lambda \in (0, \lambda_0)$ and $\det(\mathcal{A}_{12} - \lambda_0 I) = 0$.

Next, we show that the numerator in the fraction on the right-hand side of (6.18) satisfies $R(\lambda_0) \equiv a_{31}a_{12} - a_{32}(a_{11} - \lambda_0) < 0$. Indeed, using the explicit form of the coefficient of the matrix $\mathcal{A}_{12}$, we obtain

$$(6.20) \quad \lambda_0 = \frac{1}{2} \left(- \left(\frac{d_c(a - d_c)}{a} + d_b + d \right) + \sqrt{\left(\frac{d_c(a - d_c)}{a} + d_b + d \right)^2 + 4 \frac{d_c(a - d_c)(d_b + d)}{a}} \right)$$

and

$$R(\lambda_0) = -2 \frac{d_c(a - d_c)(d_b + d)}{a} + d \left(\frac{d_c(a - d_c)}{a} + \lambda_0 \right).$$

Hence, denoting $y = (d_c(a - d_c))/a$ and $D = d_b + d$ leads to

$$R(\lambda_0) = \tilde{R}(y) = -2Dy + \frac{d \left(y - D + \sqrt{(y + D)^2 + 4Dy} \right)}{2}.$$

Obviously, $\tilde{R}(0) = 0$. We leave for the reader to check that $d\tilde{R}/dy < 0$ for all $y > 0$, which implies that $\tilde{R}(y) < 0$ for all $y > 0$. This implies immediately that $R(\lambda_0) < 0$.

Hence, provided $\varepsilon > 0$ is sufficiently small, for all $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$, we obtain

$$\frac{R(\lambda)}{\det(\mathcal{A}_{12} - \lambda I)} > 0 \quad \text{and} \quad \frac{R(\lambda)}{\det(\mathcal{A}_{12} - \lambda I)} \rightarrow \infty \quad \text{as} \quad \lambda \rightarrow \lambda_0.$$

Since $\min_{x \in [0,1]} a_{23}(x) > 0$ (see (6.19)) and since $a_{33}(x)$ is a bounded function, choosing smaller $\varepsilon > 0$ (if necessary) we obtain $\min_{x \in [0,1]} q(x, \lambda) = \omega(\lambda) > 0$ for all $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$ and $\omega(\lambda) \rightarrow \infty$ for $\lambda \rightarrow \lambda_0$.

Step 2. By the Sturm-Liouville theory and Step 1, for every $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$, there exists an increasing sequence

$$0 < \mu_1(q(\cdot, \lambda)) < \mu_2(q(\cdot, \lambda)) < \dots < \mu_n(q(\cdot, \lambda)) < \dots \rightarrow +\infty$$

of eigenvalues of the problem

$$(6.21) \quad \begin{aligned} \frac{1}{\gamma} \eta'' + \mu q(x, \lambda) \eta &= 0, \quad x \in (0, 1) \\ \eta'(0) &= \eta'(1) = 0. \end{aligned}$$

Our goal is to show that there exists $\lambda_n \in (\lambda_0 - \varepsilon, \lambda_0)$ such that $\mu_n(q(\cdot, \lambda_n)) = 1$. Then, the corresponding eigenfunction of (6.21) will be a non-zero solution of (6.17).

Step 3. For each $n \in \mathbb{N}$, the quantity $\mu_n(q(\cdot, \lambda))$ is a continuous function of λ . Indeed, this is an immediate consequence of Lemma 6.5, because $q(x, \lambda)$ is a continuous function of $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$.

Step 4. Let us show that $\mu_n(\lambda) \rightarrow 0$ when $\lambda \rightarrow \lambda_0$. By Step 1, we have $\omega(\lambda) = \min_{x \in [0,1]} q(x, \lambda) \rightarrow \infty$ when $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$ and $\lambda \rightarrow \lambda_0$. Since $\omega(\lambda)$ is a positive constant for each $\lambda \in (\lambda_0 - \varepsilon, \lambda_0)$, the eigenvalues μ of the problem

$$\frac{1}{\gamma} \eta'' + \mu \omega(\lambda) \eta = 0, \quad \eta'(0) = \eta'(1) = 0.$$

are given explicitly $\mu_n(\omega(\lambda)) = n^2 \pi^2 / (\omega(\lambda) \gamma)$. Since $\omega(\lambda) \leq q(x, \lambda)$, the comparison property for eigenvalues (stated in Lemma 6.5) implies

$$\mu_n(q(\cdot, \lambda)) \leq \mu_n(\omega(\lambda)) = \frac{n^2 \pi^2}{\omega(\lambda) \gamma} \rightarrow 0 \quad \text{as} \quad \lambda \rightarrow \lambda_0.$$

Conclusion. Since $0 < \mu_1(q(\cdot, \lambda)) < \mu_2(q(\cdot, \lambda)) < \dots < \mu_n(q(\cdot, \lambda)) < \dots \rightarrow +\infty$ and $\mu_n(q(\cdot, \lambda)) \rightarrow 0$ as $\lambda \rightarrow \lambda_0$, for every $n \in \mathbb{N}$, it follows from the continuous dependence of $\mu_n(\lambda)$ on λ (see Step 3) that there exists $\lambda_n \rightarrow \lambda_0$ such that $\mu_n(\lambda_n) = 1$, provided n is sufficiently large. This completes the proof of Theorem 2.10. $\square$

Proof of Corollary 2.12. This is a consequence of Theorem 2.10 and of a general result from [3, Thm. 5.1.3] as it is explained in the paragraph following Corollary 2.12. $\square$

Proof of Corollary 2.13. Here, the analysis is similar as in the case of continuous patterns, hence, we only emphasize the most important steps.

Step 1. We fix a weak stationary solution $(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}})$ with a null set $\mathcal{I} \subset [0, 1]$. The Fréchet derivative of the nonlinear mapping $\mathcal{F} : \mathcal{H}_{\mathcal{I}} \rightarrow \mathcal{H}_{\mathcal{I}}$ defined by the mappings (f_1, f_2, f_3) in (6.1) at the point $(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}}) \in \mathcal{H}_{\mathcal{I}}$ has the form

$$D\mathcal{F}(U_{\mathcal{I}}, V_{\mathcal{I}}, W_{\mathcal{I}}) \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix} = \mathcal{A}_{\mathcal{I}}(x) \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix},$$

where $\mathcal{A}_{\mathcal{I}}(x) = \mathcal{A}(x)$ (see the matrix in (6.3)) if $x \in [0, 1] \setminus \mathcal{I}$ and

$$\mathcal{A}_{\mathcal{I}}(x) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -d_g \end{pmatrix} \quad \text{if } x \in \mathcal{I}.$$

This results immediately from the definition of the Fréchet derivative.

Step 2. Next, we study spectral properties of the linear operator

$$\mathcal{L}_{\mathcal{I}} \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \frac{1}{\gamma} \partial_x^2 \eta \end{pmatrix} + \mathcal{A}_{\mathcal{I}}(x) \begin{pmatrix} \varphi \\ \psi \\ \eta \end{pmatrix},$$

in the Hilbert space $\mathcal{H}_{\mathcal{I}}$ (see (2.33)) with the domain $D(\mathcal{L}_{\mathcal{I}}) = L_{\mathcal{I}}^2(0, 1) \times L_{\mathcal{I}}^2(0, 1) \times W^{2,2}(0, 1)$. First, we notice that the counterpart of Lemma 6.1 holds true and λ_0 (the positive eigenvalue of $\mathcal{A}_{12}$) belongs to the continuous spectrum of $(\mathcal{L}_{\mathcal{I}}, D(\mathcal{L}_{\mathcal{I}}))$. To prove this property of λ_0 , it suffices to follow the proof of Lemma 6.1.

Step 3. A complex number λ is an eigenvalue of the operator $\mathcal{L}_{\mathcal{I}}$ if and only if the following two conditions are satisfied: (i) the number λ is not an eigenvalue of the matrix $\mathcal{A}_{12}$; (ii) the boundary value problem

$$(6.22) \quad \begin{aligned} \frac{1}{\gamma} \eta'' + q_{\mathcal{I}}(\cdot, \lambda) \eta &= 0, \quad x \in (0, 1) \\ \eta'(0) = \eta'(1) &= 0 \end{aligned}$$

has a nontrivial solution. Here, we denote

$$q_{\mathcal{I}}(x, \lambda) = \begin{cases} \frac{\det(\mathcal{A}(x) - \lambda I)}{\det(\mathcal{A}_{12} - \lambda I)} & \text{if } x \in [0, 1] \setminus \mathcal{I} \\ -d_g - \lambda & \text{if } x \in \mathcal{I}. \end{cases}$$

This is the counterpart of Lemma 6.2 with an almost identical proof.

Step 4. There exists a sequence $\{\lambda_n\}_{n \in \mathbb{N}}$ of positive eigenvalues of the operator $\mathcal{L}_{\mathcal{I}}$ that satisfy $\lambda_n \rightarrow \lambda_0$ as $n \rightarrow \infty$. This is the statement of Theorem 2.10 written for discontinuous patterns and its proof follows almost the same arguments. In particular, in Step 3 of the proof of Theorem 2.10, we should use the fact the the mapping $\lambda \mapsto q_{\mathcal{I}}(\cdot, \lambda)$ is continuous in the $L^2(0, 1)$ -norm (cf. Lemma 6.5).

Step 5. Since, $-\mathcal{L}_{\mathcal{I}}$ is a sectorial operator, we complete the proof by [3, Thm. 5.1.3]. $\square$

APPENDIX A. KINETIC SYSTEM

Here, we briefly review results on the large time dynamics of solutions to reaction-diffusion equations (2.1)-(2.3) supplemented with constant initial values, namely, we consider the following system of ordinary differential equations (so-called the *kinetic system*):

$$(A.1) \quad \frac{d\bar{u}}{dt} = \left(\frac{a\bar{v}}{\bar{u} + \bar{v}} - d_c \right) \bar{u},$$

$$(A.2) \quad \frac{d\bar{v}}{dt} = -d_b \bar{v} + \bar{u}^2 \bar{w} - d\bar{v},$$

$$(A.3) \quad \frac{d\bar{w}}{dt} = -d_g \bar{w} - \bar{u}^2 \bar{w} + d\bar{v} + \kappa_0.$$

Steady states. It is easy to see that (A.1)–(A.3) has the trivial steady state $(\bar{u}_0, \bar{v}_0, \bar{w}_0) = (0, 0, \kappa_0/d_g)$. Here, the right-hand side of equation (A.1) is satisfied in the limit sense, namely, when $\bar{v} \searrow 0$ and $\bar{u} \searrow 0$. On the other hand, assuming that $a > d_c$ and

$$(A.4) \quad \kappa_0^2 \geq \Theta, \quad \text{where} \quad \Theta = 4d_g d_b \frac{d_c^2(d_b + d)}{(a - d_c)^2}$$

system (A.1)–(A.3) has two positive equilibriums $(\bar{u}_\pm, \bar{v}_\pm, \bar{w}_\pm)$, where

$$(A.5) \quad \bar{u}_\pm = \frac{a - d_c}{d_c} \bar{v}_\pm, \quad \bar{v}_\pm = \frac{d_c^2(d_b + d)}{(a - d_c)^2} \frac{1}{\bar{w}_\pm}, \quad \bar{w}_\pm = \frac{\kappa_0 \pm \sqrt{\kappa_0^2 - \Theta}}{2d_g}.$$

Indeed, for $\bar{u} \neq 0$, we obtain from equation (A.1) (with $d\bar{u}/dt = 0$) that $\bar{u} = \bar{v}(a - d_c)/d_c$. Substituting this expression to equation (A.2) (with $d\bar{v}/dt = 0$), we obtain

$$(A.6) \quad \bar{v} = \frac{d_c^2(d_b + d)}{(a - d_c)^2} \frac{1}{\bar{w}}.$$

Finally, adding equations (A.2) to equation (A.3) (with $d\bar{v}/dt = d\bar{w}/dt = 0$) and using expression (A.6) we obtain the quadratic equation

$$(A.7) \quad d_g \bar{w}^2 - \kappa_0 \bar{w} + d_b \frac{d_c^2(d_b + d)}{(a - d_c)^2} = 0.$$

It is clear that equation (A.7) has two roots $\bar{w}_\pm$ if $\kappa_0^2 > \Theta$ and one root $\bar{w}_\pm = \kappa_0/(2d_g)$ if $\kappa_0^2 = \Theta$, see (2.11)–(2.12).

Boundedness of solutions. In the following, we denote by $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ a solution of system (A.1)–(A.3) with a nonnegative initial datum.

Proposition A.1. *Every solution $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ of system (A.1)–(A.3) corresponding to a nonnegative initial datum exists for all $t > 0$. Moreover, it is nonnegative, bounded for $t > 0$, and satisfies*

$$(A.8) \quad \limsup_{t \rightarrow \infty} \bar{u}(t) \leq \frac{a\kappa_0}{\mu d_c}, \quad \frac{\kappa_0}{\nu} \leq \liminf_{t \rightarrow \infty} (\bar{v}(t) + \bar{w}(t)) \leq \limsup_{t \rightarrow \infty} (\bar{v}(t) + \bar{w}(t)) \leq \frac{\kappa_0}{\mu},$$

where $\nu = \max\{d_b, d_g\} > 0$ and $\mu = \min\{d_b, d_g\} > 0$.

Proof. The global existence of nonnegative solutions is a consequence of Theorem 3.1. To show the relations in (A.8), it suffices to follow the proof of Theorem 2.1. $\square$

Convergence to the trivial steady state. It is already proven (see Corollary 2.4 and Proposition 4.1) that the trivial steady state $(0, 0, \kappa_0/d_g)$ is locally asymptotically stable as a solution to reaction diffusion system (2.1)–(2.3). In the case of the kinetic system, we can describe more precisely the convergence of solutions towards the trivial steady state.

First, we consider the case $a < d_c$, where, by Proposition 4.1, all solutions of the reaction-diffusion system converge to the trivial steady state. Now, we improve this result for system (A.1)–(A.3)

Theorem A.2. *If $a < d_c$, then every positive solution $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ converges, as $t \rightarrow \infty$, towards $(0, 0, \kappa_0/d_g)$. Moreover,*

- if $d_c < d_b + d$, then $\bar{v}(t)/\bar{u}(t) \rightarrow 0$ as $t \rightarrow \infty$;
- if $d_c > d_b + d$ and $a > d_c - (d_b + d)$, then $\bar{v}(t)/\bar{u}(t) \rightarrow d_c(d_b + d)/(d_b + d + a - d_c)$ as $t \rightarrow \infty$;
- if $d_c > d_b + d$ and $a \leq d_c - (d_b + d)$, then $\bar{v}(t)/\bar{u}(t) \rightarrow \infty$ as $t \rightarrow \infty$.

Next, we deal with the case $a = d_c$, where the result is analogous.

Theorem A.3. *If $a = d_c$, then every positive solution $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ converges, as $t \rightarrow \infty$, towards $(0, 0, \kappa_0/d_g)$. Moreover,*

- *if $a < d_b + d$, then $\bar{v}(t)/\bar{u}(t) \rightarrow 0$ as $t \rightarrow \infty$;*
- *if $a > d_b + d$, then $\bar{v}(t)/\bar{u}(t) \rightarrow (a - (d_b + d))/(d_b + d)$ as $t \rightarrow \infty$.*

For $a > d_c$, we see from Corollary 2.4 that the trivial steady state is locally asymptotically stable. This convergence can be better described in the case of solutions of the kinetic system. Notice that if $\kappa_0^2 < \Theta$, there is no other nonnegative constant steady states of system (A.1)-(A.3).

Theorem A.4. *Assume that $a > d_c$ and $\kappa_0^2 < \Theta$. Then every positive solution $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ converges, as $t \rightarrow \infty$, towards $(0, 0, \kappa_0/d_g)$. Moreover,*

- *if $d_c < d_b + d$, then $\bar{v}(t)/\bar{u}(t) \rightarrow 0$ as $t \rightarrow \infty$;*
- *if $d_c > d_b + d$, then $\bar{v}(t)/\bar{u}(t) \rightarrow (d_c - (d_b + d))/(d_b + d + a - d_c)$ as $t \rightarrow \infty$.*

If $\kappa_0^2 \geq \Theta$, there are positive steady states defined in (A.5). Letting an initial datum $u(0)$ to be sufficiently small, we obtain that a solution converges to the trivial steady state, again.

Theorem A.5. *Assume that $a > d_c$ and $\kappa_0^2 \geq \Theta$. Let $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ be a solution to (A.1)-(A.3) corresponding to a positive initial condition $(\bar{u}(0), \bar{v}(0), \bar{w}(0))$. If $\bar{u}(0)$ satisfies*

$$\bar{u}(0) < \bar{u}_+ \equiv \frac{a - d_c}{d_c} \cdot \frac{\kappa_0 - \sqrt{\kappa_0^2 - \Theta}}{2d_b},$$

then this solution converges towards the trivial steady state. Here, $\bar{u}_+$ is the constant defined in (A.5).

Since ideas of the proofs Theorems A.2–A.5 are more-or-less the same, we are going to sketch below the proof of Theorem A.4, only. Introducing new variables $X = \bar{v}/\bar{u}$ and $Y = \bar{u}\bar{w}$ and writing, for simplicity, u instead of $\bar{u}$, we obtain the following system

$$(A.9) \quad \frac{du}{dt} = \left(\frac{aX}{1+X} - d_c \right) u,$$

$$(A.10) \quad \frac{dX}{dt} = -(d_b + d + a - d_c)X + \frac{aX}{1+X} + Y,$$

$$(A.11) \quad \frac{dY}{dt} = \left(\frac{aX}{1+X} - d_c \right) Y - d_g Y - u^2 Y + dX u^2 + \kappa_0 u$$

supplemented with positive initial conditions

$$u(0) = u_0, \quad X(0) = \frac{\bar{v}(0)}{u(0)} = X_0, \quad Y(0) = u(0)\bar{w}(0) = Y_0.$$

If $\bar{u}(t)$, $\bar{v}(t)$, and $\bar{w}(t)$ are positive of all $t > 0$, the functions $X(t)$ and $Y(t)$ are also positive. The following lemma plays an important role in the proof.

Lemma A.6. *Let $a > d_c$ and $\kappa_0^2 < \Theta$. If $X_0 < d_c/(a - d_c)$ and $Y_0 < d_c(d_b + d)/(a - d_c)$, then $X(t)$ and $Y(t)$ satisfy*

$$(A.12) \quad 0 < X(t) < \frac{d_c}{a - d_c} \quad \text{and} \quad 0 < Y(t) < \frac{d_c(d_b + d)}{a - d_c} \quad \text{for all } 0 \leq t < \infty.$$

Sketch of the proof of Lemma A.6. Since this lemma can be shown by a method similar to that from the proof of Lemma 4.3, we just mention an important point, only. Here, we derive the following inequality

$$(A.13) \quad \left[Y(t) - \frac{d_c(d_b + d)}{a - d_c} \right]_t \leq -(d_g + u_0^2) \left[Y(t) - \frac{d_c(d_b + d)}{a - d_c} \right] + R(u),$$

where

$$(A.14) \quad R(u) = -\frac{d_c d_g (d_b + d)}{a - d_c} - \frac{d_c d_b}{a - d_c} u^2 + \kappa_0 u.$$

If $R(u) \leq 0$, we immediately obtain $Y(t) < d_c(d_b + d)/(a - d_c)$ for all $t > 0$. However, it is easy to check that the assumption $\kappa_0^2 < \Theta$ implies $R(u) < 0$ for all $u > 0$. $\square$

Now, notice that, under the assumptions $a > d_c$ and $\kappa_0^2 < \Theta$, the inequality $X(t) < d_c/(a - d_c)$ implies $u_t(t) < 0$ (see eq. (A.9)). Consequently, if $X_0 < d_c/(a - d_c)$ and $Y_0 < d_c(d_b + d)/(a - d_c)$, Lemma A.6 provides an estimate of a solution $(\bar{u}(t), \bar{v}(t), \bar{w}(t))$ for $t > 0$, which allows us to show its convergence towards the trivial steady state (see the proof of Theorem 2.2). On the other hand, if either $X_0 > d_c/(a - d_c)$ or $Y_0 > d_c(d_b + d)/(a - d_c)$, one can show, by simple geometric arguments involving equations (A.9)–(A.10) and the boundedness of solutions to system (A.1)–(A.3), that there exists $T > 0$ such that $X(T) \leq d_c/(a - d_c)$ and $Y(T) \leq d_c(d_b + d)/(a - d_c)$. It is easy to see that every solution of (A.9)–(A.11) stays in the rectangle (A.12).

In order to show the convergence rate of $\bar{u}$ and $\bar{v}$ which are stated in Theorem A.4, we consider the steady states of system (A.9)–(A.11). It is clear that $(u, X, Y) = (0, 0, 0)$ is an equilibrium. Moreover, noting that $Y(t) \rightarrow 0$ as $t \rightarrow \infty$ when $u(t) \rightarrow 0$ as $t \rightarrow \infty$, we have the following *nonnegative* steady state of system (A.9)–(A.11),

$$(A.15) \quad (u, X, Y) = \left(0, \frac{d_c - (d_b + d)}{d_b + d + a - d_c}, 0 \right) \quad \text{if } d_c > d_b + d.$$

In the following, we denote by E_1 the right-hand side of (A.15). We study stability of E_1 by analyzing eigenvalues of the corresponding Jacobian matrix at the equilibrium.

Lemma A.7. *If $d_c < d_b + d$, then the equilibrium $(0, 0, 0)$ is asymptotically stable, while it is unstable if $d_c > d_b + d$. For $d_c > d_b + d$, the stationary solution E_1 is asymptotically stable.*

Proof. The Jacobian matrix J of the nonlinear mapping defined by the right-hand side of system (A.9)–(A.11) is of the form

$$J = \begin{pmatrix} \frac{aX}{1+X} - d_c & \frac{au}{(1+X)^2} & 0 \\ 0 & -(d_b + d + a - d_c) + \frac{a}{(1+X)^2} & 1 \\ -2uY + 2dXu + \kappa_0 & \frac{aY}{(1+X)^2} + du^2 & \frac{aX}{1+X} - d_c - d_g - u^2 \end{pmatrix}.$$

Hence, at the stationary solution $(0, 0, 0)$, it becomes

$$J_{(0,0,0)} = \begin{pmatrix} -d_c & 0 & 0 \\ 0 & -(d_b + d + a - d_c) & 1 \\ \kappa_0 & 0 & -d_c - d_g \end{pmatrix},$$

and it is clear that all eigenvalues of $J_{(0,0,0)}$ have negative real parts. Similarly, letting J_{E_1} to be the corresponding Jacobian matrix at the steady states E_1 , we obtain

$$J_{E_1} = \begin{pmatrix} -(d_b + d) & 0 & 0 \\ 0 & \frac{(d_b + d + a - d_c)(d_b + d - d_c)}{a} & 1 \\ \kappa_0 & 0 & -(d_b + d + d_g) \end{pmatrix}.$$

It follows from inequality $d_c > d_b + d$ that all eigenvalues of J_{E_1} are negative. $\square$

Now, the assertions in Theorem A.4 follow from Lemmas A.6 and A.7.

Remark A.8. For $\kappa_0^2 \geq \Theta$, we have $R(u) \leq 0$ (cf. (A.14)) provided $u \leq \bar{u}_+$. Therefore, under the condition $u(0) < \bar{u}_+$, we obtain the same assertion as in Lemma A.6, now however, under the assumption $a > d_c$ and $\kappa_0^2 \geq \Theta$. Here, it suffices to use the fact that $du/dt < 0$ whenever $X(t) < d_c/(a - d_c)$. Repeating the reasoning from the proof of Theorem 2.2, we can show Theorem A.5.

Stability of positive steady states. Let $(\bar{u}_\pm, \bar{v}_\pm, \bar{w}_\pm)$ be the positive steady states of system (A.1)–(A.3) given by formulas (A.5). To study their stability, we consider again system (A.9)–(A.11), which for $a > d_c$ and $\kappa_0 > \Theta$, has two positive steady states

$$(u, X, Y)_\pm = \left(\bar{u}_\pm, \frac{d_c}{a - d_c}, \frac{d_c(d_b + d)}{a - d_c} \right).$$

Theorem A.9. *The vector $(u, X, Y)_-$ is an asymptotically stable stationary solution of system (A.9)–(A.11), and $(u, X, Y)_+$ is unstable.*

Proof. First we consider Jacobian matrix J_+ of the right-hand side of (A.9)–(A.11) at $(u, X, Y)_+$:

$$J_+ = \begin{pmatrix} 0 & \frac{(a - d_c)^2}{a} \bar{u}_+ & 0 \\ 0 & -\left[d_b + d + \frac{d_c(a - d_c)}{a} \right] & 1 \\ \sqrt{\kappa_0^2 - \Theta} & \frac{d_c(a - d_c)(d_b + d)}{a} + d\bar{u}_+^2 & -d_g - \bar{u}_+^2 \end{pmatrix}.$$

Hence, every eigenvalue λ of J_+ is determined by its characteristic equation $F(\lambda) = 0$, where

$$\begin{aligned} (A.16) \quad F(\lambda) = & -\lambda^3 - \left[\bar{u}_+^2 + d_b + d + d_g + \frac{d_c(a - d_c)}{a} \right] \lambda^2 \\ & - \left[(d_g + \bar{u}_+^2) \left(d_b + d + \frac{d_c(a - d_c)}{a} \right) - \left(\frac{d_c(a - d_c)}{a} (d_b + d) + d\bar{u}_+^2 \right) \right] \lambda \\ & + \sqrt{\kappa_0^2 - \Theta} \frac{(a - d_c)^2}{a} \bar{u}_+. \end{aligned}$$

Since $F(0) > 0$ and $F(+\infty) = -\infty$, there exists at least one positive real eigenvalue. This implies that $(u, X, Y)_+$ is unstable.

Next, we investigate Jacobian matrix J_- at $(u, X, Y)_-$,

$$J_- = \begin{pmatrix} 0 & \frac{(a - d_c)^2}{a} \bar{u}_- & 0 \\ 0 & -\left[d_b + d + \frac{d_c(a - d_c)}{a} \right] & 1 \\ -\sqrt{\kappa_0^2 - \Theta} & \frac{d_c(a - d_c)(d_b + d)}{a} + d\bar{u}_-^2 & -d_g - \bar{u}_-^2 \end{pmatrix}.$$

Here, calculations are more involved to show stability of $(u, X, Y)_-$. We consider again the characteristic equation $G(\lambda) = 0$, where

$$(A.17) \quad \begin{aligned} G(\lambda) = & -\lambda^3 - \left[\bar{u}_-^2 + d_b + d + d_g + \frac{d_c(a - d_c)}{a} \right] \lambda^2 \\ & - \left[(d_g + \bar{u}_-^2) \left(d_b + d + \frac{d_c(a - d_c)}{a} \right) - \left(\frac{d_c(a - d_c)}{a} (d_b + d) + d\bar{u}_-^2 \right) \right] \lambda \\ & - \sqrt{\kappa_0^2 - \Theta} \frac{(a - d_c)^2}{a} \bar{u}_-. \end{aligned}$$

Now, for simplicity, we set $G(\lambda) = -\lambda^3 - A\lambda^2 - B\lambda - \sqrt{\kappa_0^2 - \Theta} \frac{(a - d_c)^2}{a} \bar{u}_+$. Since $A^2 - 3B > 0$, the equation $G'(\lambda) = 0$ has two negative roots

$$\lambda_1 = \frac{A + \sqrt{A^2 - 3B}}{-3}, \quad \lambda_2 = \frac{A - \sqrt{A^2 - 3B}}{-3}.$$

This implies that $G(\lambda) = 0$ has a local minimum and a local maximum in the half plane $\{\lambda : \lambda < 0\}$. Moreover, we obtain that $G(\lambda_1) < 0$ by virtue of the inequality $A^2 - 3B > 0$. Therefore, noting that $G(0) < 0$, $G(-\infty) = +\infty$ and $G(+\infty) = -\infty$, we have two possibilities:

$$\text{either } (i) \quad G(\lambda_2) \geq 0 \quad \text{or} \quad (ii) \quad G(\lambda_2) < 0.$$

Here, $G(\lambda_2)$ is given by

$$G(\lambda_2) = \lambda_2^2 \left(\frac{A + 2\sqrt{A^2 - 3B}}{3} \right) - \sqrt{\kappa_0^2 - \Theta} \frac{(a - d_c)^2}{a} \bar{u}_+.$$

If (i) occurs, then the equation $G(\lambda) = 0$ has three negative real roots, which implies immediately that $(u, X, Y)_-$ is asymptotically stable. Here, we have to notice that the case (i) occurs if κ_0^2 is sufficiently close to Θ .

Next, suppose $G(\lambda)$ satisfies (ii), namely, $G(\lambda_2) < 0$. Then, the equation $G(\lambda) = 0$ has three roots: one is real and negative, we denote it by $-\lambda_0$, and others are complex numbers μ and $\bar{\mu}$. Therefore, using the decomposition $G(\lambda) = -(\lambda + \lambda_0)(\lambda - \mu)(\lambda - \bar{\mu})$, we obtain from (A.17) that

$$A = \lambda_0 - 2\text{Re}(\mu), \quad B = |\mu|^2 - \lambda_0 2\text{Re}(\mu).$$

Now, we consider the following quantity

$$(A.18) \quad G(-A) = AB - \sqrt{\kappa_0^2 - \Theta} \frac{(a - d_c)^2}{a} \bar{u}_+.$$

Differentiating the right-hand side of (A.18) with respect to κ_0 , we obtain

$$(A.19) \quad \frac{d}{d\kappa_0} \left[AB - \sqrt{\kappa_0^2 - \Theta} \frac{(a - d_c)^2}{a} \bar{u}_+ \right] > 0 \quad \text{for all } \kappa_0^2 > \Theta.$$

Since $G(-A) > 0$ at $\kappa_0^2 = \Theta$, inequality (A.19) implies that $G(-A) > 0$ for all $\kappa_0^2 > \Theta$. Under the assumption (ii), we notice that the inequality $G(\lambda) > 0$ is satisfied only when $\lambda < -\lambda_0$. Therefore, we obtain the inequality $-A < -\lambda_0$, which is equivalent to $\lambda_0 - 2\text{Re}(\mu) > \lambda_0$. This implies $\text{Re}(\mu) < 0$. Consequently, if the case (ii) occurs, then real parts of all eigenvalues of J_- are negative, which implies that $(u, X, Y)_-$ is asymptotically stable. $\square$

Since $X = \bar{v}/\bar{u}$ and $Y = \bar{u}\bar{w}$, the steady states $(u, X, Y)_-$ and $(u, X, Y)_+$ of system (A.9)–(A.11) correspond to the steady states $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$ and $(\bar{u}_+, \bar{v}_+, \bar{w}_+)$ of (A.1)–(A.3), respectively. Here, one should recall the expressions from (A.5) to see that $\bar{u}_\pm = d_c(d_b + d)/((a - d_c)\bar{w}_\pm)$, hence,

$$\bar{u}_- = \frac{a - d_c}{d_c} \cdot \frac{\kappa_0 + \sqrt{\kappa_0^2 - \Theta}}{2d_b} \quad \text{and} \quad u_+ = \frac{a - d_c}{d_c} \cdot \frac{\kappa_0 - \sqrt{\kappa_0^2 - \Theta}}{2d_b}.$$

Let us also notice that $\bar{u}_- > \bar{u}_+$.

Thus, we have proved that stationary solutions of the original kinetic system (A.1)–(A.3) have the following stability properties.

Corollary A.10. *The vector $(\bar{u}_-, \bar{v}_-, \bar{w}_-)$ is an asymptotically stable stationary solution of system (A.1)–(A.3), while $(\bar{u}_+, \bar{v}_+, \bar{w}_+)$ is unstable.*

ACKNOWLEDGMENTS

The authors wish to express their gratitude to Steffen Härtling for his active interest in this work, his several helpful comments and discussions as well as for numerical simulations. A.
